TOPOLOGICAL EXPANSION IN THE COMPLEX CUBIC LOG-GAS MODEL. ONE-CUT CASE

PAVEL BLEHER, ALFREDO DEAÑO, AND MAXIM YATTSELEV

Dedicated to David Ruelle and Yakov Sinai

Abstract. We prove the topological expansion for the cubic log-gas partition function

$$Z_N(t) = \int_{\Gamma} \cdots \int_{\Gamma} \prod_{1 \leq j < k \leq N} (z_j - z_k)^2 \prod_{k=1}^{N} e^{-N \left( -\frac{z_j^3}{3} + \frac{tz_j}{2} \right)} \, dz_1 \cdots dz_N,$$

where $t$ is a complex parameter and $\Gamma$ is an unbounded contour on the complex plane extending from $e^{\pi i} \infty$ to $e^{\pi i/3} \infty$. The complex cubic log-gas model exhibits two phase regions on the complex $t$-plane, with one cut and two cuts, separated by analytic critical arcs of the two types of phase transition: split of a cut and birth of a cut. The common point of the critical arcs is a tricritical point of the Painlevé I type. In the present paper we prove the topological expansion for $\log Z_N(t)$ in the one-cut phase region. The proof is based on the Riemann–Hilbert approach to semiclassical asymptotic expansions for the associated orthogonal polynomials and the theory of S-curves and quadratic differentials.

1. Introduction

The main goal of this work is to analyze the topological expansion in the cubic log-gas model with a general complex coupling constant and semiclassical asymptotics of related orthogonal polynomials. The partition function of the cubic log-gas model is given as

$$Z_N(u) = \int_{\Gamma} \cdots \int_{\Gamma} \prod_{1 \leq j < k \leq N} (z_j - z_k)^2 \prod_{j=1}^{N} e^{-N \left( \frac{z_j^2}{2} - u z_j^3 \right)} \, dz_1 \cdots dz_N,$$

where $u > 0$ is a coupling constant and the contour of integration $\Gamma$ goes from $e^{\pi i} \infty$ to $e^{\pi i/3} \infty$. This work is a continuation of the works of Bleher and Deaño [6, 7].

The research of the third author (M.Y.) is supported by a grant from the Simons Foundation, CGM-354538.
As proven in [6], the free energy of the cubic log-gas model,
\begin{equation}
F_N(u) := \frac{1}{N^2} \ln \frac{Z_N(u)}{Z_N(0)},
\end{equation}
amits an asymptotic expansion as $N \to \infty$ in powers of $1/N^2$,
\begin{equation}
F_N(u) \sim \sum_{g=0}^{\infty} \frac{F^{(2g)}(u)}{N^{2g}},
\end{equation}
for any $u$ in the interval $0 \leq u < u_c$, where
\begin{equation}
u_c = \frac{3^{1/4}}{18}
\end{equation}
is a critical point. In addition, the functions $F^{(2g)}(u)$ admit an analytic continuation to the disk $|u| < u_c$ on the complex plane, and if we expand them in powers of $u$,
\begin{equation}
F^{(2g)}(u) = \sum_{j=1}^{\infty} \frac{f_{2j}^{(2g)} u^{2j}}{(2j)!},
\end{equation}
then the coefficient $f_{2j}^{(2g)}$ is a positive integer number that counts the number of 3-valent connected graphs with $2j$ vertices on a Riemann surface of genus $g$. Asymptotic expansion (1.3) is called the topological expansion. For more details on this aspect of the theory, we refer the reader to the classical papers of Bessis, Itzykson and Zuber [4], Brézin, Itzykson, Parisi and Zuber [5], the monograph of Forrester [25, Section 1.6], the works of Mulase [31], Di Francesco [17], Ercolani and McLaughlin [22, 23], and references therein, or the very readable introduction by Zvonkin [39].

As shown in [6], the coefficients $f_{2j}^{(2g)}/(2j)!$ of power series (1.5) behave, when $j \to \infty$, as
\begin{equation}
f_{2j}^{(2g)} = K_{2g} j^{5g-7} u_c^{2j} \left(1 + O(j^{-1/2})\right), \quad K_{2g} > 0.
\end{equation}
This implies that $u_c$ is the radius of convergence of power series (1.5). In fact, $u = u_c$ is a singular point of the functions (1.5). The topological expansion in a neighborhood of the critical point $u_c$ has been obtain in the work of Bleher and Deaño [7]. This topological expansion is closely related to the Painlevé I equation. The relation to the Painlevé I equation can be already seen in asymptotic formula (1.6). Namely, if we rescale the coefficients $K_{2g}$ in (1.6), by introducing the coefficients
\begin{equation}
C_{2g} = \frac{\Gamma \left(\frac{5g-1}{2}\right) u_c^g K_{2g}}{6 \cdot 3^{1/4}},
\end{equation}
and consider the following generating function:
\begin{equation}
y(t) = \sum_{g=0}^{\infty} C_{2g} t^{1-\frac{5g}{2}},
\end{equation}
then $y(t)$ solves the Painlevé I differential equation,
\begin{equation}
y''(t) = a_0 y^2(t) - a_1 t,
\end{equation}
with $a_0 = 2^\frac{3}{2} 3^\frac{3}{4}$, $a_1 = 2^\frac{5}{2} 3^{\frac{1}{4}}$ (see [3, 21, 6]).

It is noteworthy that the key ingredient in the proof of topological expansion (1.3) in [6] is the derivation of semiclassical asymptotic formulae for the recurrence coefficients $\gamma_n^2$, $\beta_n$ of the corresponding monic orthogonal polynomials $P_n(z) = z^n + \ldots$. The orthogonality condition is stated on the contour $\Gamma$:
\begin{equation}
\int_{\Gamma} P_n(z) z^k w(z) dz = 0, \quad k = 0, 1, \ldots, n - 1; \quad w(z) = e^{-N \left(\frac{z^2}{4} + u z^3\right)}
\end{equation}
Namely, as proven in [6], for any $u$ such that $0 \leq u < u_c$, there exists $\varepsilon > 0$ such that as $N, n \to \infty$ with $1 - \varepsilon \leq \frac{n}{N} \leq 1 + \varepsilon$, the recurrence coefficients $\gamma_n^2$ and $\beta_n$ admit the
asymptotic expansions in powers of $\frac{1}{N}$:

\[
\begin{align*}
\gamma_n^2 &\sim \sum_{k=0}^{\infty} \frac{1}{N^{2k}} g_{2k}(\frac{n}{N}, u), \\
\beta_n &\sim \sum_{k=0}^{\infty} \frac{1}{N^{2k}} b_{2k}(\frac{n}{N} + \frac{1}{2N}, u),
\end{align*}
\]  

(1.11)

where the functions $g_{2k}(s, u)$, $b_{2k}(s, u)$, $k = 0, 1, \ldots$, do not depend on $n$ and $N$ and are analytic in $s$ at $s = 1$.

In the paper [7] this asymptotic expansion is extended to the double scaling asymptotic expansion of the recurrence coefficients at the critical point $u_c$. In the double scaling regime we set

\[
\frac{n}{N} = 1 + v N^{-4/5},
\]

(1.12)

where $v \in \mathbb{R}$ is a scaling variable. Then as proven in [7], at $u = u_c$ the recurrence coefficients $\gamma_n^2$ and $\beta_n$ admit the asymptotic expansions in powers of $N^{-2/5}$ as $N \to \infty$:

\[
\begin{align*}
\gamma_n^2 &\sim \gamma_c^2 + \sum_{k=1}^{\infty} \frac{1}{N^{2(k-1/5)}} p_{2k}(v), \\
\beta_n &\sim \beta_c + \sum_{k=1}^{\infty} \frac{1}{N^{2(k-1/5)}} q_{2k}(\tilde{v}),
\end{align*}
\]

(1.13)

where the functions $p_{2k}(v)$, $q_{2k}(\tilde{v})$ are expressed in terms of the Boutroux tritronquée solution to Painlevé I and $\tilde{v} = v + \frac{\lambda N^{-1/5}}{2}$. As shown in [7], expansions (1.11) and (1.13) can be extended for large $N$ to $u$ in overlapping intervals, $[0, u_c - N^{-0.79}]$ for (1.11) and $[u_c - N^{-0.65}, u_c]$ for (1.13), and this can be used to obtain the double scaling asymptotic formula for the partition function.

Namely, let $u - u_c = C \lambda N^{-\frac{1}{5}}$, where $C = 2^{-\frac{1}{2}} 3^{-\frac{1}{2}}$ and $\lambda$ is a complex scaling variable in the double scaling regime. Then for $\lambda$ outside of a neighborhood of the poles of the Boutroux tritronquée solution to Painlevé I $y(\lambda)$, the partition function $Z_N(u)$ can be written as

\[
Z_N(u) = Z_N^{\text{reg}}(u) Z_N^{\text{sing}}(\lambda) \left(1 + \mathcal{O}(N^{-\varepsilon})\right), \quad \varepsilon > 0,
\]

(1.14)

where the regular factor is

\[
Z_N^{\text{reg}}(u) = e^{N^2 [a + b(u-u_c) + c(u-u_c)^2] + d},
\]

(1.15)

with some explicit constants $a, b, c, d$, and the singular factor is

\[
Z_N^{\text{sing}}(\lambda) = e^{-Y(\lambda)},
\]

(1.16)

where $Y(\lambda)$ is a solution of the differential equation

\[
y''(\lambda) = y(\lambda),
\]

(1.17)

with the boundary condition

\[
y(\lambda) = \frac{2\sqrt{6}}{45} (-\lambda)^{5/2} - \frac{1}{48} \log(-\lambda) + \mathcal{O}((-\lambda)^{-5/2}), \quad \lambda \to -\infty.
\]

Asymptotic formula (1.14) is used in [7] to prove the conjecture of David [12, 13] that the poles of $y(\lambda)$ give rise to zeros of $Z_N(u)$.

This work is a continuation of [6, 7]. The main goal of it is to investigate the topological expansion of the cubic log-gas model for complex values of $u$. Formula (1.1) is not very convenient for this purpose because the contour of integration $\Gamma$ should be rotated to secure the convergence of the integral. Instead, let us make the change of variables in (1.1),

\[
z_j = (3u)^{-1/3} \zeta_j + \frac{1}{6u},
\]

(1.19)

where we assume that $u > 0$ and $(3u)^{-1/3} > 0$. Then

\[
\frac{z_j^2}{2} - uz_j^3 - \frac{1}{108u^2} = -\frac{c_j^3}{3} + t \zeta_j,
\]

(1.20)
where
\[ t = \frac{1}{4(3u)^{4/3}}, \]
and with the help of the Cauchy theorem, formula (1.1) can be reduced to
\[ Z_N(u) = C_N \int_{\Gamma} \cdots \int_{\Gamma} \prod_{1 \leq j < k \leq N} (c_j - c_k)^2 \prod_{k=1}^N e^{-N\left(-\frac{z_j^2}{2} + t\gamma_k\right)} d\zeta_1 \cdots d\zeta_N, \]
where \( C_N \) is an explicit constant. Now the integral converges for any complex \( t \).

The primary interest of the present study is the asymptotic analysis of the partition function
\[ Z_N(t) := \int_{\Gamma} \cdots \int_{\Gamma} \prod_{1 \leq j < k \leq N} (z_j - z_k)^2 \prod_{k=1}^N e^{-NV(z;t)} dz_1 \cdots dz_N, \]
with respect to the parameter \( t \in \mathbb{C} \) for the case when
\[ V(z; t) = -\frac{z^3}{3} + tz, \quad t \in \mathbb{C}, \]
where \( \Gamma \) is an unbounded smooth contour such that for any parametrization \( z(s), s \in \mathbb{R}, \) of \( \Gamma \) there exists \( \epsilon \in (0, \pi/6) \) and \( s_0 > 0 \) for which
\[ \left\{ \begin{array}{ll}
\arg(z(s)) - \pi/3 & \leq \pi/6 - \epsilon, \quad s \geq s_0, \\
\arg(z(s)) - \pi & \leq \pi/6 - \epsilon, \quad s \leq -s_0,
\end{array} \right. \]
where \( \arg(z(s)) \in [0, 2\pi) \). The above conditions ensure that the partition function \( Z_N(t) \) is finite and due to analyticity of the integrand does not depend on a particular \( \Gamma \) satisfying (1.25). Hence, we shall denote by \( \mathcal{T} \) the collection of all such contours.

We analyze the partition function via the corresponding monic orthogonal polynomials
\[ \int_{\Gamma} z^k P_n(z; t, N)e^{-NV(z;t)} dz = 0, \quad k \in \{0, \ldots, n - 1\}. \]
Due to the non-Hermitian character of the above relations, it might happen that polynomial satisfying (1.26) is non-unique. In this case we understand by \( P_n(z; t, N) \) the monic polynomial of the smallest degree (such a polynomial is always unique). One way of connecting \( Z_N(t) \) to \( P_n(z; t, N) \) is via \textit{three term recurrence relation}. More precisely, it is known that
\[ zP_n(z; t, N) = P_{n+1}(z; t, N) + \beta_n(t, N)P_n(z; t, N) + \gamma_n^2(t, N)P_{n-1}(z; t, N), \]
granted all the polynomials in (1.27) have prescribed degrees, where
\[ \left\{ \begin{array}{ll}
\gamma_n^2(t, N) & = h_n(t, N)/h_{n-1}(t, N), \\
h_n(t, N) & = \int_{\Gamma} P_n^2(z; t, N)e^{-NV(z;t)} dz.
\end{array} \right. \]
Observe that if \( P_n(z; t, N) = P_{n+1}(z; t, N) \) with both polynomials having degree \( n \), then \( h_n(t, N) = 0 \) and \( h_{n+1}(t, N) = \infty \). More generally, it holds that \( h_n(t, N) \) is a meromorphic function of \( t \) and so is \( \gamma_n^2(t, N) \). It is further known that the recurrence coefficients \( \gamma_n^2(t, N) \) satisfy the \textit{Toda equation},
\[ \frac{\partial^2 F_N(t)}{\partial t^2} = \gamma_n^2(t, N), \quad F_N(t) = \frac{1}{N^2} \log Z_N(t). \]

Another way of connecting \( Z_N(t) \) to orthogonal polynomials is through the formula
\[ Z_N(t) = N! \prod_{n=0}^{N-1} h_n(t, N), \]
where \( h_n(t, N) \) are given in (1.28). However, we shall not elaborate on this approach.

The structure of the paper is as follows:
- In Sections 2 and 3 we describe equilibrium measures and corresponding \( S \)-curves for the cubic model under consideration. This leads us to a precise description of the phase diagram of the cubic model on the complex \( t \)-plane.
• In Section 4 we present the main results of the paper: the topological expansion in the one-cut phase region and the asymptotic expansion of the orthogonal polynomials and their recurrence coefficients.
• In Section 5 we obtain various results about the detailed structure of the S-curves and critical graphs of the quadratic differential.
• In Section 6 we evaluate the g-function and its asymptotic behavior at singular points.
• In Section 7 we apply the Riemann–Hilbert approach to derive the asymptotic behavior of the orthogonal polynomials and their recurrence coefficients.
• And finally, in Section 8 we prove the topological expansion in the one-cut phase region.

2. Equilibrium Measures and S-Property

It is well understood that the zeros of polynomials satisfying (1.26) asymptotically distribute as a certain weighted equilibrium measure on an S-contour corresponding to the weight function (1.24). In this section we discuss these notions in greater detail. Our consideration will use the recent works of Huybrechs, Kuijlaars, and Lejon [27] and Kuijlaars and Silva [30]. Let us start with some definitions.

**Definition 2.1.** Let $V$ be an entire function. The logarithmic energy in the external field $\Re V$ of a measure $\nu$ in the complex plane is defined as

$$E_V(\nu) = \iint |\log |s - t|| d\nu(s)d\nu(t) + \int \Re V(s)d\nu(s).$$

The equilibrium energy of a contour $\Gamma$ in the external field $\Re V$ is equal to

$$\mathcal{E}_V(\Gamma) = \inf_{\nu \in \mathcal{M}(\Gamma)} E_V(\nu),$$

where $\mathcal{M}(\Gamma)$ denotes the space of Borel probability measures on $\Gamma$.

When $\Re V(s) - \log |s| \to +\infty$ as $\Gamma \ni s \to \infty$, there exists a unique minimizing measure for (2.1), which is called the weighted equilibrium measure of $\Gamma$, say $\mu_{\Gamma}$, in the external field $\Re V$, see [34, Theorem I.1.3] or [27]. We shall use this definition in the case of the cubic polynomial (1.24) and $\Gamma \in \mathcal{T}$. The support of $\mu_{\Gamma}$, say $J_{\Gamma}$, is a compact subset of $\Gamma$. The equilibrium measure $\mu = \mu_{\Gamma}$ is characterized by the Euler–Lagrange variational conditions:

$$2U^\mu(z) + \Re V(z) \begin{cases} = \ell, & z \in J_{\Gamma}, \\ \geq \ell, & z \in \Gamma \setminus J_{\Gamma}, \end{cases}$$

where $\ell = \ell_{\Gamma}$ is a constant, the Lagrange multiplier, and

$$U^\mu(z) = -\int \log |z - s|d\mu(s)$$

is the logarithmic potential of $\mu$, see [34, Theorem I.3.3]. Any $\Gamma \in \mathcal{T}$ can be used to define $Z_N(t)$ in (1.23), nevertheless, it is well understood in the theory of non-Hermitian orthogonal polynomials, starting with the works of Stahl [35, 36, 37] and Gonchar and Rakhmanov [26] that one should use the contour whose equilibrium measure has support symmetric (with the S-property) in the external field $\Re V$. We make this idea precise in the following definition.

**Definition 2.2.** The support $J_{\Gamma}$ has the S-property in the external field $\Re V$, if it consists of a finite number of open analytic arcs and their endpoints, and on each arc it holds that

$$\frac{\partial}{\partial n_+} (2U^\mu + \Re V) = \frac{\partial}{\partial n_-} (2U^\mu + \Re V),$$

where $\frac{\partial}{\partial n_+}$ and $\frac{\partial}{\partial n_-}$ are the normal derivatives from the (+)- and (−)-side of $\Gamma$. We shall say that a curve $\Gamma \in \mathcal{T}$ is an S-curve in the field $\Re V$, if $J_{\Gamma}$ has the S-property in this field.

It is also understood that geometrically $J_{\Gamma}$ is comprised of critical trajectories of quadratic differentials. Recall that if $Q$ is a meromorphic function, a trajectory (resp. orthogonal trajectory) of a quadratic differential $-Q(z)dz^2$ is a maximal regular arc on which

$$-Q(z(s))(z'(s))^2 > 0 \quad \text{(resp.} \quad -Q(z(s))(z'(s))^2 < 0)$$
for any local uniformizing parameter. A trajectory is called critical if it is incident with a finite critical point (zero or a simple pole of \(-Q(z)dz^2\)) and it is called short if it is incident only with finite critical points. We designate the expression critical (orthogonal) graph of \(-Q(z)dz^2\) for the totality of the critical (orthogonal) trajectories \(-Q(z)dz^2\).

The following theorem is a specialization to \(V(z;t)\) of [30, Theorem 2.3].

**Theorem 2.3.** Let \(V(z;t)\) be given by (1.24).

1. There exists a contour \(\Gamma_t \in \mathcal{T}\) such that

\[
\mathcal{E}_V(\Gamma_t) = \sup_{\Gamma \in \mathcal{T}} \mathcal{E}_V(\Gamma).
\]

2. The equilibrium measure \(\mu_t := \mu_{\Gamma_t}\) is the same for every \(\Gamma_t\) satisfying (2.4). The support \(J_t\) of \(\mu_t\) has the S-property in the external field \(\text{Re} V(z;t)\).

3. The function

\[
Q(z;t) = \left( \frac{V'(z;t)}{2} - \int \frac{d\mu_t(s)}{z-s} \right)^2, \quad z \in \mathbb{C} \setminus J_t,
\]

is a polynomial of degree 4.

4. The support \(J_t\) consists of short critical trajectories of the quadratic differential \(-Q(z;t)dz^2\) that connect simple zeros of \(Q(z;t)\) and the equation

\[
d\mu_t(z) = \frac{1}{\pi i} Q^{1/2}(z;t)dz, \quad z \in J_t,
\]

holds on each such critical trajectory, where \(Q^{1/2}(z;t) = \frac{1}{2}z^2 + \mathcal{O}(z)\) as \(z \to \infty\).

Much information on the structure of the critical graphs of a quadratic differential can be found in the excellent monographs [28, 33, 38]. Since \(\deg Q(z) = 4\), \(J_t\) consists of one or two arcs, corresponding (respectively) to the cases where \(Q(z)\) has two simple zeros and one double zero, and the case where it has four simple zeros. In this paper we study the case of a single arc and investigate the two-cut case in a later publication. In the next section we discuss which values of \(t\) correspond to the one-cut case and describe the geometry of the critical graphs in more detail.

3. Structure of \(\Gamma_t\)

The structure of \(\Gamma_t\) and its dependence on \(t\) has been heuristically described in [1, 2]. Our goal here is to provide rigorous mathematical justifications for this description, when \(J_t\) consists of a single arc. Clearly, in this case \(Q(z;t)\) should be of the form

\[
Q(z;t) = \frac{1}{4}(z-a(t))(z-b(t))(z-c(t))^2.
\]

It follows from (2.5) in conjunction with (1.24) that

\[
Q(z;t) = \left( \frac{-z^2 + t}{2} - \frac{1}{z} + \mathcal{O}(z^{-2}) \right)^2 = \frac{(z^2 - t)^2}{4} + z + C.
\]

Thus, by equating the coefficients in (3.1) and (3.2), we obtain a system of equations

\[
\begin{cases}
a + b + 2c = 0, \\
ab + c^2 + 2(a+b)c = -2t, \\
2abc + (a+b)c^2 = -4.
\end{cases}
\]

By setting \(x := (a+b)/2\) and eliminating the product \(ab\) from the second and third relations in (3.3), we get that

\[
x^3 - tx - 1 = 0.
\]

To study the solutions of (3.4), denote by \(C\) the critical graph of an auxiliary quadratic differential

\[
- (1 + 1/s)^3 ds^2,
\]

see Figure 2(a). We show in Section 5 that \(C\) consists of 5 critical trajectories emanating from \(-1\) at the angles \(2\pi k/5\), \(k \in \{0, \ldots, 4\}\), one of them being \((-1,0)\), other two forming
a loop crossing the real line approximately at 0.635, and the last two approaching infinity along the imaginary axis without changing the half-plane (upper or lower). Given \( C \), define

\[
\begin{align*}
\Delta &:= \{ x : 2x^3 \in C \}.
\end{align*}
\]

Further, put \( \Omega_{\text{one-cut}} \) to be the shaded region on Figure 2(b) and set

\[
\partial \Omega_{\text{one-cut}} = \Delta_{\text{birth}}^b \cup \{ -2^{-1/3} \} \cup \Delta_{\text{split}} \cup \{ e^{\pi i/3} 2^{-1/3} \} \cup \Delta_{\text{birth}}^a,
\]

where \( \Delta_{\text{split}} \) connects \(-2^{-1/3}\) and \( e^{\pi i/3} 2^{-1/3} \), \( \Delta_{\text{birth}}^b \) extends to infinity in the direction of the angle \( 7\pi/6 \) while \( \Delta_{\text{birth}}^a \) extends to infinity in the direction of the angle \( \pi/6 \). Finally, let

\[
t(x) := \left( x^3 - 1 \right)/x
\]

and set

\[
\begin{align*}
t_{cr} &:= 3 \cdot 2^{-2/3} = t \left( -2^{-1/3} \right), \\
O_{\text{one-cut}} &:= t(\Omega_{\text{one-cut}}), \\
C_{\text{split}} &:= t(\Delta_{\text{split}}), \\
C_{\text{birth}}^a &:= t(\Delta_{\text{birth}}^a), \\
C_{\text{birth}}^b &:= t(\Delta_{\text{birth}}^b), \\
S := (t_{cr}, \infty), \\
e^{2\pi i/3} S &:= \{ z : e^{-2\pi i/3} z \in S \},
\end{align*}
\]

see Figure 3. The function \( t(x) \) is holomorphic in \( \Omega_{\text{one-cut}} \) with non-vanishing derivative there. It maps \( \Omega_{\text{one-cut}} \) onto \( O_{\text{one-cut}} \) in a one-to-one fashion. Hence, the inverse map \( x(t) \) exists and is holomorphic. Altogether, the following proposition holds.

**Proposition 3.1.** There exists a holomorphic branch \( x(t) \) of (3.4) that maps \( O_{\text{one-cut}} \) conformally onto \( \Omega_{\text{one-cut}} \). The function \( x(t) \) possesses analytic continuations across each of
the arcs \( C_{\text{split}}, C_{\text{birth}}^{0}, \) and \( C_{\text{birth}}^{1} \). The functions

\[
\begin{cases}
a(t) := x(t) - i\sqrt{2}/\sqrt{2}(t), \\
b(t) := x(t) + i\sqrt{2}/\sqrt{2}(t), \\
c(t) := -x(t),
\end{cases}
\]

(3.7)

are holomorphic in \( O_{\text{one-cut}} \), where \( \sqrt{x}(t) \) is the branch holomorphic in \( O_{\text{one-cut}} \) satisfying \( \sqrt{x}(0) = e^{i\pi/3} \). It is a matter of a routine verification to check that they also satisfy (3.3).

Below, we adapt the following convention: \( \Gamma(z_{1}, z_{2}) \) (resp. \( \Gamma[z_{1}, z_{2}] \)) stands for the trajectory or orthogonal trajectory (resp. the closure of) connecting \( z_{1} \) and \( z_{2} \), oriented from \( z_{1} \) to \( z_{2} \), and \( \Gamma(z, e^{i\theta}\infty) \) (resp. \( \Gamma(e^{i\theta}\infty, z) \)) stands for the orthogonal trajectory ending at \( z \), approaching infinity at the angle \( \theta \), and oriented away from \( z \) (resp. oriented towards \( z \)).

![Schematic representation of the critical (solid) and critical orthogonal (dashed) graphs of \(-Q(z; t)dz^2\) when \( t \in O_{\text{one-cut}} \). The bold curves represent the preferred S-curve \( \Gamma_{t} \). Shaded region is the set where \( \text{Re} \left( \int_{0}^{t} Q^{1/2}(z; t)dz \right) < 0 \).](image)

**Theorem 3.2.** Let \( \mu_{t} \) and \( Q(z; t) \) be as in Theorem 2.3, \( J_{t} = \text{supp}(\mu_{t}) \). When \( t \in \overline{O_{\text{one-cut}}} \), the polynomial \( Q(z; t) \) is of the form (3.1) with \( a(t) \), \( b(t) \), and \( c(t) \) as in Proposition 3.1 and the set \( J_{t} \) consists of a single arc. Moreover,

(I) if \( t \in O_{\text{one-cut}} \), then \( J_{t} = \Gamma[a, b] \) and an S-curve \( \Gamma_{t} \in \mathcal{T} \) can be chosen as

(a) \( \Gamma(e^{i\pi}\infty, a) \cup J_{t} \cup \Gamma(b, e^{i\pi/3}\infty) \) when \( t \) belongs to the connected component bounded by \( S \cup C_{\text{crit}} \cup e^{2i\pi/3}S \), see Figure 4(a–e);

(b) \( \Gamma(e^{i\pi}\infty, a) \cup J_{t} \cup \Gamma(b, c) \cup \Gamma(c, e^{i\pi/3}\infty) \) when \( t \in S \), see Figure 4(f);

(c) \( \Gamma(e^{i\pi}\infty, c) \cup \Gamma(c, a) \cup J_{t} \cup \Gamma(b, e^{i\pi/3}\infty) \) when \( t \in e^{2i\pi/3}S \);

(d) \( \Gamma(e^{i\pi/2}, a) \cup J_{t} \cup \Gamma(b, e^{-i\pi/3}\infty) \cup \Gamma(e^{-i\pi/3}\infty, c) \cup \Gamma(c, e^{i\pi/3}\infty) \) when \( t \) belongs to the connected component bounded by \( S \cup C_{\text{birth}}^{0} \), see Figure 4(g);

(e) \( \Gamma(e^{i\pi}\infty, c) \cup \Gamma(c, e^{-i\pi/3}) \cup \Gamma(e^{-i\pi/3}\infty, a) \cup J_{t} \cup \Gamma(b, e^{i\pi/3}\infty) \) when \( t \) belongs to the connected component bounded by \( e^{2i\pi/3}S \cup C_{\text{birth}}^{0} \).

(II) if \( t = t_{a} \) (resp. \( t = e^{2i\pi/3}t_{a} \)), then \( J_{t} = \Gamma[a, b] \), \( c \) coincides with \( b \) (resp. \( a \)), and an S-curve \( \Gamma_{t} \in \mathcal{T} \) can be chosen as in Case I(a), see Figure 5(a).

(III) if \( t \in C_{\text{split}} \), then \( J_{t} = \Gamma[a, c] \cup \Gamma[c, b] \) and an S-curve \( \Gamma_{t} \in \mathcal{T} \) can be chosen as in Case I(a), see Figure 5(b).

\(^{1}\)This notation is unambiguous as the corresponding trajectories are unique for polynomial differentials as follows from Teichmüller’s lemma, see (5.1) further below.
(IV) if \( t \in \mathcal{C}^b \) (resp. \( t \in \mathcal{C}^a \)), then \( J_t = \Gamma[a,b] \) and an S-curve \( \Gamma_t \in \mathcal{T} \) can be chosen as in Case I(d) (resp. Case I(e)), see Figure 5(c).

We prove Theorem 3.2 in Section 5.

![Figure 5](image-url)

**Figure 5.** This is a continuation of Figure 4 for the case \( t \in \partial \mathcal{O}_{\text{one-cut}} \).

**Remark 3.3.** Even though we shall not dwell on this point here, the reason for the nomenclature introduced above is the following. When \( t \notin \mathcal{O}_{\text{one-cut}} \), the double zero \( c(t) \) splits into two simple zeros, say \( c_1(t) \) and \( c_2(t) \). When \( t \) crosses \( \mathcal{C}_{\text{split}} := \mathcal{C}_{\text{birth}}^a \cup \mathcal{C}_{\text{birth}}^b \), a critical trajectory connecting \( c_1 \) and \( c_2 \) will appear while \( a \) and \( b \) will remain being connected by a trajectory.

Let us elaborate on all the configurations appearing on Figures 4 and 5. To this end,

![Figure 6](image-url)

**Figure 6.** Schematic representations of (a) the set \( S \) (dashed lines); (b) the sets \( \Delta^\perp \) (dashed lines) and \( \Delta_{\text{crit}} \) (solid curves within the shaded region); (c) the images of \( \Delta^\perp \) and \( \Delta_{\text{crit}} \) under \( t(x) \).

we need to introduce the totality of the orthogonal trajectories of the differential (3.5) emanating out of \(-1\), say \( S \), see Figure 6(a), the sets

\[
\Delta_{\text{crit}} := \Delta \cap \Omega_{\text{one-cut}}, \quad \Delta^\perp := \{ x : 2x^3 \in S \} \cap \Omega_{\text{one-cut}},
\]

see Figure 6(b), as well as the sets

\[
t(\Delta_{\text{crit}}) =: C_{\text{crit}}^a \cup C_{\text{crit}}^b, \quad t(\Delta^\perp) =: \mathcal{S}_{\text{crit}}^a \cup \mathcal{S}_{\text{crit}}^b \cup S \cup e^{2\pi i/3}S,
\]

where \( C_{\text{crit}}^a, C_{\text{crit}}^b \) and \( \mathcal{S}_{\text{crit}}^a, \mathcal{S}_{\text{crit}}^b \) are incident with \( t_{\text{cr}} \) and \( e^{2\pi i/3}t_{\text{cr}} \), respectively, see Figure 6(c).

**Theorem 3.4.** The critical and critical orthogonal graphs of \(-Q(z; t)dz^2\) have the structure as on

- Figure 5(a,b,c) when \( t = t_{\text{cr}}, t \in \mathcal{C}_{\text{split}}, \) and \( t \in \mathcal{C}_{\text{birth}}^b \); respectively;
- Figure 4(f,d,b) when \( t \in S, t \in \mathcal{S}_{\text{crit}}^a, \) and \( t \in \mathcal{C}_{\text{crit}}^b \); respectively;
- Figure 4(g) when \( t \) belongs to the component of \( \mathcal{O}_{\text{one-cut}} \) bounded by \( S \cup \mathcal{C}_{\text{birth}}^b \);
• Figure 4(e) when \( t \) belongs to the component of \( \mathcal{O}_{\text{one-cut}} \) bounded by \( S \cup C^b_{\text{crit}} \); in fact, \( C^b_{\text{crit}} \) is the reflection of \( C^b_{\text{birth}} \) across the real line and the structure is the same as on Figure 4(g) reflected across the real line as well;
• Figure 4(c) when \( t \) belongs to the component of \( \mathcal{O}_{\text{one-cut}} \) bounded by \( C^b_{\text{crit}} \cup S^b_{\text{crit}} \);
• Figure 4(a) when \( t \) belongs to the component of \( \mathcal{O}_{\text{one-cut}} \) bounded by \( S^b_{\text{crit}} \cup S^a_{\text{crit}} \).

In the rest of the cases one needs to pick the reflection of \( t \) across the line \( L_{x/3} \), where
\[
L_\theta := \{ re^{i\theta} : r \in (-\infty, \infty) \},
\]
and then reflect the corresponding graph structures across the line \( L_{2x/3} \). This symmetry is displayed on Figures 4(a) and 5(a).

We prove Theorem 3.4 in Section 5 as well.

4. Main Results

In what follows, we always assume that \( t \in \partial \mathcal{O}_{\text{one-cut}} \) while \( \beta_n(t,N) \) and \( \gamma_n(t,N) \) are recurrence coefficients (1.27) of the polynomials \( P_n(z; t, N) \) satisfying orthogonality relations (1.26) with \( V(z; t) \) as in (1.24) on a contour \( \Gamma = \Gamma_t \) as in Theorem 3.2.

Henceforth, we use interval notation preceded by \( \Gamma_t \) to denote subarcs of \( \Gamma_t \). For example, \( \Gamma_t(u, v] \) stands for the subarc of \( \Gamma_t \) connecting \( u \) and \( v \), not containing \( u \) and containing \( v \), and \( u \) precedes \( v \) according to the orientation of \( \Gamma_t \).

Below, we prove existence of various expansions that depend on the parameter \( t \). To indicate the way of dependence, we introduce the following two notions.

Definition 4.1. Given an increasing sequence \( \alpha(i) \to \infty \) as \( i \to \infty \), we say that an expansion
\[
A_N(t) \sim \sum_{i=0}^{\infty} A(i)(t) N^{-\alpha(i)}
\]
holds \( t \)-locally uniformly if for any \( T \subset \partial \mathcal{O}_{\text{one-cut}} \) such that \( T \cap O_{\text{one-cut}}, T \cap C_{\text{split}}, T \cap C_{\text{birth}} \) are compact, there exist constants \( C_T(T) < \infty \) for which
\[
|A_N(t) - \sum_{i=0}^{I-1} A(i)(t) N^{-\alpha(i)}| \leq C_T(T) N^{-\alpha(I)}, \quad t \in T.
\]

Moreover, we say that an expansion is strongly \( t \)-locally uniform if \( C_T(T) < \infty \) exists as long as \( T \cap C_{\text{split}} \) is compact, \( T \cap C_{\text{birth}} \) is closed, and there exists \( \epsilon(T) > 0 \) for which
\[
\Re \left( \int_{b(t)}^{c(t)} Q^{1/2}(z; t) \, dz \right) \leq -\epsilon(T)
\]
for all \( t \in T \cap O_{\text{one-cut}} \) large with \( \arg(t) \in (0, \pi/2) \).

To understand (4.1) geometrically, notice that its left-hand side is equal to 0 when \( t \in \partial O_{\text{one-cut}} \cup C^\alpha_{\text{crit}} \cup C^b_{\text{crit}}, \) see Figures 3 and 6(c), is positive when \( t \) belongs to the part of \( O_{\text{one-cut}} \) bounded by \( C^\alpha_{\text{crit}} \cup C_{\text{split}} \cup C^b_{\text{crit}}, \) and is negative otherwise. Thus, (4.1) describes the way \( T \) is separated from \( C_{\text{birth}} \) when it extends to the point at infinity.

For functions that depend both on the parameter \( t \) and variable \( z \), we adopt the following conventions.

Definition 4.2. We say that the equality \( f_N(z; t) = \mathcal{O}(N^{-\alpha}) \) holds \((z,t)\)-locally uniformly for \( z \in V \) as \( N \to \infty \) if for each \( T \) such that \( T \cap O_{\text{one-cut}}, T \cap C_{\text{split}}, T \cap C_{\text{birth}} \) are compact, and any collection of compact sets \( \{K_t\}_{t \in T} \) such that \( K_t \subset V \), there exists \( C(V; T) < \infty \) for which
\[
|f_N(z; t)| \leq C(V; T) N^{-\alpha}, \quad z \in K_t, \quad t \in T,
\]
for all \( N \) large. Similarly, the notion of a property holding strongly \((z,t)\)-locally uniformly for \( z \in V \) should be straightforward in the view of Definition 4.1.
4.1. Asymptotic expansion of \( F_N(t) \).

**Theorem 4.3.** Let \( F_N(t) \) be the free energy \((1.29)\). Then it holds uniformly on subsets of \( O_{\text{one-cut}} \) satisfying \((4.1)\) that

\[
F_N(t) \sim \sum_{k=0}^{\infty} F^{(2k)}(t) N^{-2k},
\]

where the functions \( F^{(2k)}(t) \) are holomorphic in \( O_{\text{one-cut}} \) and extend holomorphically across each of the arcs \( C_{\text{birth}}, C_{\text{split}}^a, \) and \( C_{\text{split}}^b \). In particular, it holds that

\[
F^{(0)}(t) = 1 - \frac{2}{3} x^3(t) - \frac{1}{2} \log(-2x(t)) + \int_0^t \int_0^\tau \left( - \frac{1}{2x(\sigma)} + \frac{7x'(\sigma) + 2x x''(\sigma)}{6} \right) \mathrm{d}\sigma \mathrm{d}\tau,
\]

where \( x'(t) \) is the derivative of \( x(t) \) with respect to \( t \) and the integrals can be computed along any path in \( O_{\text{one-cut}} \).

Functions \( F^{(2k)}(t) \) encode information on the number of certain graphs on a Riemann surface of genus \( k \).

**Remark 4.4.** If we relabel the functions \( F^{(2g)} \) in \((1.5)\) by \( \hat{F}^{(2g)} \), then it holds that

\[
\begin{align*}
\hat{F}^{(0)}(y) &:= \frac{3}{4} y^{3/2} - \frac{1}{2} \log(4t) - F^{(0)}(t), \quad y^{-1} = 3(4t)^{3/4}, \\
\hat{F}^{(2g)}(y) &:= F^{(2g)}(t), \quad g \geq 1.
\end{align*}
\]

We prove Theorem 4.3 in Section 8 using Toda equations \((1.29)\) and the asymptotic expansion of the recurrence coefficients.

4.2. Asymptotic expansion of \( \gamma_n^2(t;N) \) and \( \beta_n(t;N) \).

**Theorem 4.5.** Let \( x(t) \) be as in Proposition 3.1. Assuming that \(|n - N| \leq N_0\) for some absolute constant \( N_0 \), it holds that

\[
\begin{align*}
\gamma_n^2(t, N) &\sim -\frac{1}{2x(t)} + \sum_{k=1}^{\infty} G_{\alpha,k}(t; n - N) N^{-\alpha_k}, \\
\beta_n(t, N) &\sim x(t) + \sum_{k=1}^{\infty} B_{\alpha,k}(t; n - N) N^{-\alpha_k},
\end{align*}
\]

for some explicitly computable \( G_{\alpha,k} \) and \( B_{\alpha,k} \), where the expansions are \( t \)-locally uniform and

\[
\alpha_t = 1, \quad \alpha_t = 1/2, \quad \text{and} \quad \alpha_t = 1/5
\]

for \( t \in O_{\text{one-cut}}, \) \( t \in C_{\text{birth}} \cup C_{\text{split}}, \) and \( t \in \{t_{\text{cr}}, e^{2\pi i/3} t_{\text{cr}}\} \), respectively. Moreover, the expansion of \( \gamma_n^2(t, N) \) is strongly \( t \)-locally uniform. The functions \( G_k(t; n - N) \) and \( B_k(t; n - N) \) are holomorphic in \( O_{\text{one-cut}}, \) can be holomorphically continued across each of the arcs \( C_{\text{split}}, C_{\text{birth}}, \) and \( C_{\text{birth}}, \) and

\[
\begin{align*}
G_{(2j-1)/5}(t; 0) &\equiv 0, \quad t \in \{t_{\text{cr}}, e^{2\pi i/3} t_{\text{cr}}\}, \\
G_{2j-1}(t; 0) &\equiv 0, \quad t \in O_{\text{one-cut}}, \quad j \in \mathbb{N}.
\end{align*}
\]

Using (4.4) we can deduce certain analyticity properties of \( \gamma_n^2(t, N) \).

**Remark 4.6.** The partition function \( Z_N(t) \) is an entire function of the parameter \( t \). Hence, it follows from Toda equation \((1.29)\) that \( \gamma_n^2(t, N) \) is a meromorphic function of \( t \). Moreover,

\[
\gamma_n^2(t, N) = -\frac{1}{2x(t)} + O(N^{-1})
\]

strongly \( t \)-locally uniformly in \( O_{\text{one-cut}} \) by (4.4). Hence, for any closed set \( T \subset O_{\text{one-cut}} \) satisfying \((4.1)\), there exists an integer \( N(T) \) such that \( \gamma_n^2(t, N) \) is holomorphic on \( T \) for all \( N \geq N(T) \), i.e., on some neighborhood of \( T \) that belongs to \( O_{\text{one-cut}} \).
Observe that the recurrence coefficients for different parameters \( N \) are related. Indeed, given \( N_1 \) and \( N_2 \), it holds that

\[
\begin{align*}
P_n(z; t_1, N_1) &= (N_2/N_1)^{n/3}P_n(w; t_2, N_2), \\
\gamma_n^2(t_1, N_1) &= (N_2/N_1)^{2/3}\gamma_n^2(t_2, N_2), \\
\beta_n(t_1, N_1) &= (N_2/N_1)^{1/3}\beta_n(t_2, N_2),
\end{align*}
\]

where \( w := (N_1/N_2)^{1/3}z \) and \( t_2 := (N_1/N_2)^{2/3}t_1 \), as follows from (1.26) and (1.27). Hence, given \( N \) and \( t \in O_{\text{one-cut}} \), asymptotic expansions (4.4) can be expanded to a larger range of indices \( n \) than those covered by Theorem 4.5.

**Remark 4.7.** Put \( \mathcal{N} := \{ (u, t) : t \in O_{\text{one-cut}}, u \in \mathcal{N}_t \} \), where \( \mathcal{N}_t \) is the largest open subset of \( \mathbb{C} \setminus (-\infty, 0] \) such that \( ut \in O_{\text{one-cut}} \) for all \( u \in \mathcal{N}_t \) (clearly, \( 1 \in \mathcal{N}_1 \)). Define

\[
\begin{align*}
\hat{G}_{2k}(t, u) &:= u^{3k-1}G_{2k}(ut; 0), \\
\tilde{B}_k(t, u) &:= u^{(3k-1)/2}B_k(ut; 0),
\end{align*}
\]

where we take the principal root of \( u^{(3k-1)/2} \), which are holomorphic functions in \( N \). Then, it follows from (4.4), (4.6), and (4.7), applied with \( N_1 = N \) and \( N_2 = n \), that

\[
\begin{align*}
\gamma_n^2(t, N) &\sim \frac{-1}{2ux(ut)} + \sum_{k=1}^{\infty} \hat{G}_{2k}(t, u)N^{-2k}, \\
\beta_n(t, N) &\sim \frac{x(ut)}{\sqrt{u}} + \sum_{k=1}^{\infty} \tilde{B}_k(t, u)N^{-k},
\end{align*}
\]

whenever \( (n/N)^{-2/3} \in \mathcal{N}_t \), where the expansions are locally uniform in \( t \) and \( u \).

In fact, following [8, Section 5], we can improve on the expansion of \( \beta_n(t, N) \).

**Theorem 4.8.** There exist holomorphic in \( N \) functions \( \hat{B}_{2k}(t, v) \) such that

\[
\beta_n(t, N) \sim \sum_{k=0}^{\infty} \hat{B}_{2k}(t, v)N^{-2k}, \quad v = \left( \frac{n + 1/2}{N} \right)^{-2/3},
\]

whenever \( (n + 1/2/N)^{-2/3} \in \mathcal{N}_t \), where the expansion is locally uniform in \( t \) and \( v \).

Theorems 4.5 and 4.8 are proven in Section 8.

4.3. **Strong asymptotics of** \( P_n(z; t, N) \). To describe the asymptotics of the orthogonal polynomials themselves, we need to introduce complexified equilibrium potential

\[
g(z; t) := \int \log(z - s)d\mu_t(s), \quad z \in \mathbb{C} \setminus \Gamma_t(e^{\pi i}\infty, b],
\]

where we take the principal branch of \( \log(\cdot - s) \) holomorphic outside of \( \Gamma_t(e^{\pi i}\infty, s] \) and \( \mu_t \) is the equilibrium measure defined in (2.6). Since \( \mu_t \) is a probability measure, it holds that

\[
e^g(z; t) = z + O(1) \quad \text{as} \quad z \to \infty
\]

and this function is holomorphic in \( \mathbb{C} \setminus J_t \). In fact, the function \( e^g \) can be written explicitly.

**Proposition 4.9.** Let, as before, \( a(t) \) and \( b(t) \) be the endpoints of \( J_t \), see (3.7). In what follows, we set

\[
\sqrt{(z - a(t))(z - b(t))} \sim z \quad \text{as} \quad z \to \infty
\]
to be the square root with the branch cut along \( J_t \). Then the function

\[
D(z; t) := \exp \left\{ 3V(z; t) - 2x^3(t) + (z^2 + xz(t) - 2t)\sqrt{(z - a(t))(z - b(t))} \right\}/6
\]

is holomorphic in \( \mathbb{C} \setminus J_t \). Moreover, it is non-vanishing there, \( D(\infty; t) = 1 \), and it has continuous traces on \( J_t \) that satisfy

\[
D_+(s; t)D_-(s; t) = \exp \left\{ V(s; t) - 2x^3(t)/3 \right\}, \quad s \in J_t.
\]
That is, \( D(z; t) \) is the Szegö function of \( V(\cdot; t)\big|_{J_t} \) normalized to have value 1 at infinity. Furthermore, it holds that
\[
e^{g(z;t)} = \frac{D(z; t) A(z; t)}{\sqrt{2x(t)} B(z; t)},
\]
where the functions \( A \) and \( B \) are defined by
\[
\begin{align*}
A(z; t) &:= \frac{1}{2} \left( \left( \frac{z-b(t)}{z-a(t)} \right)^{1/4} + \left( \frac{z-a(t)}{z-b(t)} \right)^{1/4} \right), \\
B(z; t) &:= \frac{i}{2} \left( \left( \frac{z-b(t)}{z-a(t)} \right)^{1/4} - \left( \frac{z-a(t)}{z-b(t)} \right)^{1/4} \right),
\end{align*}
\]
and the branches of the 1/4-roots are principal and have the branch cuts along \( J_t \); in particular, \( A(\infty; t) = 1 \) and \( B(\infty; t) = 0 \). The function \( F(z; t) := -iA(z; t)/B(z; t) \) can be equivalently written as
\[
F(z; t) = \frac{2}{b(t) - a(t)} \left( z - \frac{b(t) + a(t)}{2} + \sqrt{(z - a(t))(z - b(t))} \right)
\]
and is holomorphic and non-vanishing in \( \mathbb{C} \setminus J_t \) has a simple pole at infinity, and its traces on \( J_t \) multiply to 1.

We prove Proposition 4.9 in Section 6.

**Theorem 4.10.** Let \( \alpha_t \) be as in Theorem 4.3 and \( |N-n| \leq N_0 \) for some fixed constant \( N_0 \). Then
\[
\begin{align*}
P_n(z; t, N) &= \left( 1 + O(N^{-\alpha_t}) \right) A(z; t) D^{N-n}(z; t) e^{n g(z; t)}, \quad (z, t)\text{-locally uniformly for } z \in \mathbb{C} \setminus J_t \text{ (or } z \in \mathbb{C} \setminus (J_t \cup \{c\}) \text{ when } t \in C_{\text{split}} \text{)}, \quad \text{where } \mathcal{O}\text{-term vanishes at } z = \infty. \quad \text{In particular, } \deg(P_n(z; t, N)) = n \text{ for all } N \text{ large. Moreover,}
\end{align*}
\]
\[
\begin{align*}
P_n(s; t, N) &= \left( 1 + O(N^{-\alpha_t}) \right) A_+(s; t) D^{N-n}(s; t) e^{n g_+(s; t)} + \left( 1 + O(N^{-\alpha_t}) \right) A_-(s; t) D^{N-n}(s; t) e^{n g_-(s; t)}, \quad (s, t)\text{-locally uniformly for } s \in \Gamma_1(a, b) \text{ (or } s \in \Gamma_1(a, c) \cup \Gamma_1(c, b) \text{ when } t \in C_{\text{split}} \text{). When } n = N, \mathcal{O}\text{-terms in (4.17) and (4.18) are strongly } (z, t)\text{-locally uniform.}
\end{align*}
\]

Theorem 4.10 is proven in Section 7. Combining Theorem 4.10 with observation (4.7), we obtain the following corollary.

**Corollary 4.11.** Given \( t \in O_{\text{one-cut}} \), assume that \( u := \lim_{N \to \infty} (n/N)^{-2/3} \) exists and \( u \in O_{\text{one-cut}} \). Then it holds locally uniformly in \( \mathbb{C} \setminus J_{ut} \) that
\[
u^{n/2} P_n(z/\sqrt{u}; t, N) = (1 + o(1)) A(z; ut) e^{n g(z; ut)}.
\]

5. S-curves

For brevity, we set \( \varpi_t := -Q(z; t)dz^2 \).

5.1. Critical graphs: local structure. The differential \( \varpi_t \) has two critical points of order 1, namely \( a, b \), a critical point of order 2, namely \( c \), (unless \( c \) coincides with either \( a \) or \( b \) in which case \( \varpi_t \) has critical points of orders 1 and 3), and a critical point of order \(-8\) at infinity. All other points are regular with respect to \( \varpi_t \) (order 0).

Through each regular point of \( \varpi_t \), passes exactly one trajectory and one orthogonal trajectory, which are orthogonal to each other at the point. Two distinct (orthogonal) trajectories meet only at critical points [38, Theorem 5.5].

As \( Q(z; t) \) is a polynomial, no finite union of (orthogonal) trajectories can form a closed Jordan curve while a trajectory and an orthogonal trajectory can intersect at most once [33, Lemmas 8.3]. Furthermore, (orthogonal) trajectories of \( \varpi_t \) cannot be recurrent (dense in two-dimensional regions) [28, Theorem 3.6].

If \( z_0 \in \{a, b, c\} \) has order \( m \), there are \( m + 2 \) critical trajectories emanating from \( z_0 \) at angles
\[
((2k + 1)\pi - \arg Q^{(m)}(z_0; t))/(m + 2), \quad k \in \{0, \ldots, m + 1\},
\]
see [38, Theorem 7.1]. Thus, there are 3 critical trajectories of $\varpi_t$, emanating from $a$, 3 critical trajectories emanating from $b$, and 4 emanating from $c$ (under the condition $c \neq a, b$). Since the point at infinity is a pole of order 8, there are 6 distinguished directions, namely, 

$$\pi/6 + k\pi/3, \quad k \in \{0, \ldots, 5\},$$

in which the trajectories can approach it. Moreover, there is a neighborhood of infinity such that every trajectory entering this neighborhood necessarily tends to infinity, [38, Theorem 7.4]. The above discussion applies to the orthogonal trajectories as well. In particular, they can approach infinity only at the angles $k\pi/3, k \in \{0, \ldots, 5\}$.

A geodesic polygon with respect to $\varpi_t$ is a Jordan curve in $\mathbb{C}$ that consists of a finite number of trajectories and orthogonal trajectories of $\varpi_t$. According to Teichmüller’s lemma [38, Theorem 14.1], it holds that

$$\sum_{z \in P} \left(1 - \frac{\text{ord}(z)}{2\pi} \right) = 2 + \sum_{z \in \text{int}(P)} \text{ord}(z),$$

where $P$ is a geodesic polygon, ord is order of $z$ with respect to $\varpi_t$, and $\theta(z) \in [0, 2\pi]$, $z \in P$, is the interior angle of $P$ at $z$. Clearly, both sums in (5.1) are finite as only critical points of $z_\omega$ and vertices of the polygon have a non-zero contribution.

To simplify the forthcoming discussion, let us observe that the differential $\varpi_t$ possesses several symmetries. Firstly, notice that when $t$ belongs to the subregion of $O_{\text{one-cut}}$ bounded by $C^i$, see Figures 3 and 6(c), we have

$$x(i) = \overline{x(i)} \quad \Rightarrow \quad \varpi_t(z) = \overline{\varpi_t(z)}.$$  

That is, for such $t$, the critical (orthogonal) graph coincides with the reflection across the real axis of the critical (orthogonal) graph for $i$. Secondly, it holds that

$$x(te^{2\pi i/3}) = \overline{x(t)e^{4\pi i/3}} \quad \Rightarrow \quad \varpi_t(z) = \overline{\varpi_{te^{2\pi i/3}}(fe^{4\pi i/3})}.$$

That is, the critical (orthogonal) graph for $t$ coincides with the reflection across the line $L_{2\pi i/3}$, see (3.8), of the critical (orthogonal) graph for $i \gamma_{e^{2\pi i/3}}$ (which is the reflection of $t$ across the line $L_{\pi/3}$). Symmetries (5.2) and (5.3) yield that we need to concern ourselves only with the case

$$x \in \mathbb{R}_{\text{one-cut}} \quad \text{and} \quad 2\pi/3 \leq \arg(x) \leq \pi.$$ 

Notice also that (5.2) and (5.3) are precisely the symmetries described in Theorem 3.4.

5.2. Critical graphs via level lines. To continue, it will be convenient to observe the following. Let $R(z) := \sqrt{(z - a)(z - b)}$ be the branch holomorphic outside of some arc, say $\gamma_{ab}$, joining $a$ and $b$ and such that $R(z) = z + O(1)$ as $z \to \infty$. Expressing $a$, $b$, and $c$ through $x$ via (3.7), we have

$$z \to \infty.$$ 

as $z \to \infty$. Therefore, the function

$$I_x(z) := \int_b^z (s + x)R(s)ds = 2 \int_b^z Q^{1/2}(s; t)ds$$

is defined up to an addition of an integer multiple of $4\pi i$ (depending on the path of integration) and is analytic (multi-valued) in $\mathbb{C} \setminus \gamma_{ab}$. From the previous subsection we know that there are 3 trajectories emanating from $a$ and the three from $b$. As there are only three finite critical points, there always exists at least one trajectory out of $a$ and at least one trajectory out of $b$ that extends to infinity. Pick one such trajectory for $a$, say $\gamma_a$. Then $I_x(z)$ is a well-defined holomorphic function in $\mathbb{C} \setminus (\gamma_a \cup \gamma_{ab})$. Write,

$$U_x(z) := \text{Re}(I_x(z)) \quad \text{and} \quad V_x(z) := \text{Im}(I_x(z)),$$

Then we can see from (5.6) that $U_x(z)$ is a harmonic function in $\mathbb{C} \setminus \gamma_{ab}$ while $V_x(z)$ can be defined harmonically in $\mathbb{C} \setminus (\gamma_a \cup \gamma_{ab})$. Since $U_x(a) = U_x(b) = 0$, the zero level set of $U_x$ contains the trajectories emanating from both $a$ and $b$ and is independent of the choice of
\( \gamma_{ab} \) (the analytic continuation of \( I_x(z) \) across \( \gamma_{ab} \) is given by \( -I_x(z) \) that preserves the zero level set of \( U_x \)). Similarly, the orthogonal trajectories out of \( b \) are part of the zero level set of the selected branch of \( V_x \) while the orthogonal trajectories out of \( a \) are part of \( 2\pi \) and \(-2\pi\)-level sets of \( V_x \).

It is obvious from their definition that the harmonic functions \( U_x \) continuously depend on the parameter \( x \). Hence, their corresponding level sets converge to each other in Hausdorff metric on any compact subset of \( \mathbb{C} \) (to see this around \( \gamma_{ab} \), recall that \( U_x \) can always be harmonically continued across \( \gamma_{ab} \)). Moreover, if we subtract from \( U_x \) the real part of the polynomial part of the first two terms in \((5.6)\) and \( \log|z| \), the obtained function will be harmonic at infinity and will continuously depend on \( x \). Therefore, we can control the behavior of the level sets of \( U_x \) not only on compact subsets of \( \mathbb{C} \) but around the point at infinity as well. Thus, if for some fixed \( x_0 \) all four critical trajectories out of \( c = -x_0 \) approach infinity, then the critical trajectories out of \( c = -x \) will approach infinity in the same directions for all \( x \) in a small neighborhood of \( x_0 \). Hence, if \( x \) belongs to an open connected set on which \( U_x(-x) \neq 0 \) (this necessarily implies that trajectories out of \( c \) cannot end at \( a \) or \( b \)), then the trajectories out \( c \) approach infinity in the same directions for each \( x \) on this set. Similar considerations hold for \( V_x \) as well.

### 5.3. Critical graphs: transitions

It follows from the previous subsection the structure of the critical (orthogonal) graph can change only when \( U_x(c) = 0 \) \( (V_x(c) = 0, \pm 2\pi) \). Let us identify for which \( x \) these harmonic functions vanish at \( c \). From the choice of the branch of the square root we have that \( R(-x) = -2x^{1/2} + 1/2x^3 \), where the root is equal to 1 when \( x = \infty \). Moreover, we see from \((5.4)\) that we are interested only in the values \( \Im(x^3) \geq 0 \). Hence,

\[
I_x(-x) = \frac{-8x^3}{3} \left( 1 + \frac{1}{2x^3} \right)^{3/2} + 4x^3 \left( 1 + \frac{1}{2x^3} \right)^{1/2} + \log \left( \frac{1 + \sqrt{1 + 1/2x^3}}{1 - \sqrt{1 + 1/2x^3}} \right)
\]

where the path of integration lies in the upper half-plane. That is, we need to understand the integral \((5.7)\) of the quadratic differential \((3.5)\) in the upper half plane. From the general principles, we see that \( U_x(-x) = 0 \) \( (V_x(-x) = 0) \) if and only if \( 2x^3 \) belongs to a (orthogonal) trajectory emanating from \(-1\).

Differential \((3.5)\) has a zero of order 3 at \(-1\), a pole of order 3 at the origin, and a pole of order 4 at infinity. Thus, there are 5 trajectories emanating from \(-1\), one of which is clearly \((-1,0)\). There is one distinguished approach of the origin, which is necessarily along the negative real axis since \((-1,0)\) is a trajectory. There are two distinguished directions at infinity, which are along the imaginary axis. Moreover, according to the three pole theorem \([28, \text{Theorem 3.6}]\), this differential does not have any recurrent trajectories. The last fact implies that the four trajectories out of \(-1\) (excluding \((-1,0)\)) either approach infinity or form loops. Going through the possible cases and using Teichmüller’s lemma, we see that the trajectories emanating from \(-1\) at the angles \( \pm 2\pi/5 \) form a loop\(^2\), and the other two approach infinity (it is a simple calculus exercise to see that they cannot touch the real line). Hence, Figure 2(a) is indeed correct.

On the other hand, the local structure of the critical orthogonal trajectories near critical points must be the same. It is obvious that \((-\infty,-1)\) and \((0,\infty)\) are critical orthogonal trajectories. Thus, by repeating the same analysis, we get that the critical orthogonal graph is as on Figure 6(a) with the orthogonal trajectory \((0,\infty)\) not displayed.

Combining the above analysis with explicit computations and \((5.7)\), we see that the values of \( U_x(c) \) and \( V_x(c) \) are as displayed on Figure 7.

### 5.4. Critical graph: global structure

Let \( \Delta_{\text{split}} \) and \( \Delta_{\text{birth}} \) be as defined before \((3.6)\), while \( \Delta_{\text{crit}} \) as defined before Theorem 3.4. Write \( \Delta_{\text{crit}} = \Delta_{\text{crit}}^{a} \cup \Delta_{\text{crit}}^{b} \), where \( \Delta_{\text{crit}}^{a} \) and \( \Delta_{\text{birth}} \) are incident with the same point, see Figure 8. Then it follows from the preceding subsection\(^2\)The loop crosses the real line approximately at 0.6349131623.
that

\[ U_x(c) = 0 \iff x \in \Delta_{\text{birth}}^a \cup \Delta_{\text{birth}}^b \cup \Delta_{\text{crit}}^a \cup \Delta_{\text{crit}}^b \cup \{ -2^{1/3} \} \cup \{ 2^{1/3}e^{\pi i/3} \}. \]

Denote by \( \Omega_e \) the subdomain of \( \Omega_{\text{one-cut}} \) bounded by \( \Delta_{\text{birth}}^e \) and \( \Delta_{\text{crit}}^e \), \( e \in \{a,b\} \), and by \( \Omega_{ab} \) the subdomain bounded by \( \Delta_{\text{crit}}^a \), \( \Delta_{\text{crit}}^b \), and \( \Delta_{\text{split}} \), see Figure 8. Recall that we only need to study the cases when \( x \) satisfies (5.4).

Let \( x \in \Omega_{ab} \). From what precedes we know that the trajectories out of \( c \) approach infinity in the same four directions. The case \( x \in U_{2\pi/3} \), see (3.8), has been worked out in [27] (to obtain the setting of [27] one needs to perform the transformations \( z \mapsto e^{\pi i/6}z \) and \( t \mapsto e^{\pi i/3}K \) in (1.24)). It was shown that there exists \( r^* \) such that for \( x = r^*e^{2\pi i/3} \), \( r < r^* \), there are no critical trajectory of \( \omega_c \), connecting \( a \) and \( b \) and for \( r > r^* \) such a trajectory exists and the critical (orthogonal) graph is as on Figure 4(a). Thus, the trajectories out of \( c \) approach infinity at the angles

\[ 7\pi/6 + k\pi/3, \quad k \in \{0,1,2,3\}, \]

for each \( x \in \Omega_{ab} \). Now, if there always exists a trajectory connecting \( a \) and \( b \), the other two trajectories out of \( b \) must approach infinity at the angles \( \pi/6 \) and \( \pi/2 \) and the trajectories out of \( a \) must approach infinity at the angles \( 5\pi/6 \) and \( 7\pi/6 \) by Teichmüller’s lemma (5.1), which would finish the description of the critical graph in this case.

Assume to the contrary that such a trajectory does not exist. It follows from Teichmüller’s lemma that both \( a \) and \( b \) must belong to the sector of opening \( \pi \) at infinity delimited by the trajectories out of \( c \). In this case two trajectories out one of the points \( a,b \) will approach infinity in the directions \( 5\pi/6 \) and \( 7\pi/6 \), forming a sector say \( X_a \), and two trajectories of the other point will approach infinity in the directions \( \pi/6 \) and \( \pi/2 \), forming a sector say \( X_b \), see Figure 9. We further can choose the arc \( \gamma_{ab} \) outside of \( X_a \cup X_b \), that is, belonging to geodesic polygon with four corners \( a,b,\infty,\infty \) and respective angles \( 2\pi/3, 2\pi/3, 0, 0 \), see the dashed arc on Figure 9. Denote by \( X \) the region that does not contain \( c \) and is bounded by \( \gamma_{ab} \) and a part of \( \partial X_a \cup \partial X_b \). As trajectories cannot intersect, \( X \) contains one trajectory arc, say \( T \).
Recall that around each simple zero of $\varpi_t$, the differential can be written as $(3/2)^2 \zeta \mathrm{d}\zeta^2$ for some local parameter $\zeta$, [38, Theorem 6.1]. This means that $I_x(z)$ has constant sign locally in $X_a$ and $X_b$, but it also is continuous and cannot vanish there. Hence, it has a constant sign in each of these sectors. As we can always choose a branch of the logarithm in (5.6) so that $I_x(z)$ is holomorphic in the closure $X_a \cup X \cup X_b$, we have $I_x(z) = z^3(1/3 + o(1))$ as $z \to \infty$ uniformly in $X_a \cup X \cup X_b$. Thus, $U_x(z)$ has the same sign in $X_a$ and $X_b$. The same local structure and continuity yield that $U_x(z)$ has the opposite sign in $X \setminus T$ and is zero on $T$ by construction. As $U_x(z)$ is harmonic in $X$, the latter contradicts the maximum principle and therefore our assumption is false. Therefore, when $x \in \Omega_{ab}$ the critical graph of $\varpi_t$ has indeed the structure as on Figure 4(a,b,c).

Let $x \in \Omega_{b}$, which is also connected. The case $x \in L_\pi \cap \Omega_{\text{one-cut}}$ has been investigated in [6]. It was shown that the critical and critical orthogonal graphs are as on Figure 4(f) when $x \in L_\pi \cap \Omega_{b}$ and Figure 5(a) when $x = -2^{1/3}$. This fixes the behavior of the trajectories out of $c$. Arguing as in the previous paragraph, we get that $a$ and $b$ must be connected by a trajectory and therefore the behavior of the whole critical graph is fixed, see Figure 4(e,f,g).

Let now $x \in \Delta^b_{\text{crit}}$. Continuity with respect to parameter implies that the structure of the critical graph should be obtained through the limiting process from within both $\Omega_{ab}$ and $\Omega_{b}$, which necessarily yields that it must be as on Figure 4(d).

Finally, let $x \in \Delta_{\text{split}}$. Denote by $\Omega_{a}$ a domain whose boundary contains $\Delta_{\text{split}}$ that has empty intersection with $\Omega_{\text{one-cut}}$ and $\Delta$ (defined after (3.4)), see Figure 8. It was shown in [27] that the critical graph and critical orthogonal graphs for $x \in L_{2\pi/3} \cap \Omega_{a}$ are as in Figure 10. Hence, the trajectories out of $c$ approach infinity in the directions $-\pi/6$, $\pi/2$, $5\pi/6$, and $3\pi/2$. It follows from Teichmüller’s lemma (5.1) that the points $a$ and $b$ must be separated by the trajectories out of $c$. Hence, there are no trajectory joining $a$ and $b$. Continuity with respect to the parameter immediately yields that the critical graph of $\varpi_t$ is as on Figure 5(b) when $x \in \Delta_{\text{split}}$.

5.5. Critical orthogonal graph: global structure. In what follows we shall refer to the key observation: given an unbounded domain whose boundary consists of critical trajectories that are consecutive at each point of intersection (such intersections have zero contribution to the left-hand side of (5.1) and the two trajectories extending to infinity necessarily form
an angle of magnitude \(\pi/3\) there), (5.1) implies that any orthogonal trajectory entering this domain will remain inside. Recall further, that orthogonal trajectories cannot intersect.

![Figure 11](image)

**Figure 11.** The dashed lines are those where \(V_x(c) = 0\), solid lines are those where \(U_x(c) = 0\), and \(V_x(c) = -\pi\) on the dashed-dotted line. The shaded region is the one from (5.4).

Let \(x \in L_{2\pi/3} \cap \overline{\Gamma_{\text{one-cut}}}\). In this case the graphs must be symmetric with respect to the line \(L_{2\pi/3}\) by (5.3). This symmetry, the global structure of the critical graph, and the key observation yield that the orthogonal critical graph is as on Figure 4(a) or Figure 5(b).

When \(x \in \Delta_{\text{crit}}^b\), the global structure of the critical graph and key observation along fix the critical orthogonal graph to be as on Figure 4(d), see also Figure 4(c,e).

Consider \(x\) in the region bounded by \(L_{2\pi/3}\) and \(\Delta_{\text{crit}}^b\). The critical graph is always the same, see Figure 4(a,b,c). The key observation fixes three orthogonal trajectories out of \(c\) except for the one, say \(T_x\), that becomes \(\Gamma(c, e^{2\pi i/3}\infty)\) when \(x \in L_{2\pi/3} \cap \overline{\Gamma_{\text{one-cut}}}\), see Figure 4(a), and becomes \(\Gamma(c, e^{\pi i/3}\infty)\) when \(x \in \Delta_{\text{crit}}^b\), see Figure 4(d). Notice also that fixing \(T_x\) fixes the entire critical orthogonal graph as orthogonal trajectories cannot intersect. Observe also that besides becoming a short orthogonal trajectory \(\Gamma(c)\), those are the only options for \(T_x\). Indeed, it could have happened that \(T_x = \Gamma(c, e^{\pi i/3}\infty)\), but then it would necessarily hold that \(T_x = \Gamma(c, b)\) for some \(x\) by continuity. In this case we would have \(V_x(c) = -2\pi\), which is impossible as \(V_x(c) \geq -\pi\) in the considered region, see Figures 7 and 11. Thus, the critical graph is as on Figure 4(a,b,c) in the considered region. Since \(V_x(c) < 0\) when \(T_x = \Gamma(c, e^{2\pi i/3}\infty)\), \(V_x(c) = 0\) when \(T_x = \Gamma(c, b)\), and \(V_x(c) > 0\) when \(T_x = \Gamma(c, e^{\pi i/3}\infty)\), the corresponding claims of Theorem 3.4 follow.

When \(x \in L_{\pi} \cap \overline{\Gamma_{\text{one-cut}}}\), we know that the critical orthogonal graph must be symmetric with respect to the real axis by (5.2). This symmetry, the global structure of the critical graph, and the key observation imply that the critical orthogonal graph must be as on Figure 4(f) or Figure 5(a).

Finally, let \(x\) belong to the region bounded by \(L_{\pi} \cap \overline{\Gamma_{\text{one-cut}}}\) and \(\Delta_{\text{crit}}^b\). Since the critical graph is always the same, the critical orthogonal graph can be only as on Figure 4(e,f,g). Continuity considerations similar to the ones above imply that it is as on Figure 4(e) for the considered \(x\). This finishes the proof of Theorem 3.4 and therefore of Theorem 3.2.

6. \(g\)-Function

In this section we discuss properties of \(g(z;t)\) defined in (4.10). We consider the parameter \(t \in \overline{\Omega_{\text{one-cut}}}\) to be fixed and stop indicating the dependence on \(t\) of the various quantities appearing below whenever this does not introduce ambiguity.

6.1. Global properties. It follows directly from definition (4.10) that

\[
\partial_z g(z;t) = \int \frac{d\mu_s(s)}{z - s},
\]

where \(\partial_z := (\partial_x - i\partial_y)/2\). Therefore, we can deduce from (2.2) and (2.5) that

\[
g(z;t) = \frac{V(z;t) - \ell^*_t}{2} + \int_{b} Q^{1/2}(s;t)ds,
\]

where, as usual, we take the branch \(Q^{1/2}(z;t) = \frac{1}{2}z^2 + O(z)\), and \(\ell^*_t\) is a constant such that \(\Re(\ell^*_t) = \ell_t\) (the explicit expression for \(\ell^*_t\) can be obtained from (5.6) and the fact that
$g(z; t) = \log z + O(z^{-1})$ as $z \to \infty$. In the view of (6.1), define
\begin{equation}
(6.2) \quad \phi_c(z) := 2 \int_c^z Q^{1/2}(s; t) ds, \quad e \in \{a, b\},
\end{equation}
holomorphically in $\mathbb{C} \setminus \Gamma_t [b, e^{\pi i/3} \infty]$ when $e = b$, and in $\mathbb{C} \setminus \Gamma_t (e^{\pi i \infty}, a)$ when $e = a$ (observe that (5.6) provides an explicit formula for these functions). It follows from (2.6) and (6.2) that
\begin{equation}
(6.3) \quad \begin{cases}
\phi_b(z) = \phi_a(z) \pm 2\pi i, & z \in \mathbb{C} \setminus \Gamma_t, \\
\phi_{b+}(s) = \pm 2\pi i \mu_t (\Gamma_t[s, b]), & s \in \Gamma_t(a, b),
\end{cases}
\end{equation}
where, in the first relation, the plus sign is used if $z$ lies to the left of $\Gamma_t$ and the minus sign if $z$ lies to the right of $\Gamma_t$. By combining (6.1) and (6.3) we get that
\begin{equation}
(6.4) \quad g_+(s; t) - g_-(s; t) = \begin{cases}
0, & s \in \Gamma_t(b, e^{\pi i/3} \infty), \\
\pm \phi_{b+}(s), & s \in \Gamma_t(a, b), \\
2\pi i, & s \in \Gamma_t(e^{\pi i \infty}, a),
\end{cases}
\end{equation}
and that
\begin{equation}
(6.5) \quad g_+(s; t) + g_-(s; t) - V(s; t) + \ell_t = \begin{cases}
\phi_b(s), & s \in \Gamma_t(b, e^{\pi i/3} \infty), \\
0, & s \in \Gamma_t(a, b), \\
\phi_a(s), & s \in \Gamma_t(e^{\pi i \infty}, a).
\end{cases}
\end{equation}

To control the error terms in Theorem 4.10, we need to have precise information on the behavior of $\phi_c$ around $a$, $b$, and $c$, when the latter belongs to $\Gamma_t$. This is exactly the goal of the following two subsections.

6.2. Local analysis at $e \in \{a, b\}$, $e \neq c$. Given $e \in \{a, b\}$, $e \neq c$, set
\begin{equation}
(6.6) \quad U_e := \{z : |z - e| < \delta_e \rho(t)|a - b|\},
\end{equation}
where $\delta_e \in (0, 1]$ to be adjusted later and we shall specify the function $\rho(t)$ further below in Section 6.4. Define
\begin{equation}
(6.7) \quad J_e := U_e \cap J_t \quad \text{and} \quad I_e := U_e \cap (\Gamma_t \setminus J_t),
\end{equation}
where the arcs $J_e$ and $I_e$ inherit their orientation from $\Gamma_t$. Since $I_e$ is a subarc of the orthogonal trajectory of $w_t = -Q(z; t) dz^2$, it holds that
\begin{equation}
(6.8) \quad \phi_c(s) < 0, \quad s \in I_e.
\end{equation}
Moreover, we get from (6.3) that
\begin{equation}
(6.9) \quad \phi_{c+}(s) = \pm 2\pi i \epsilon_e \mu_t (J_{s,c}) = 2\pi i e^{\pm \epsilon_e} \frac{\partial}{\partial z} |\mu_t (J_{s,c})|
\end{equation}
where $J_{s,c}$ is the subarc of $J_e$ with endpoints $e$ and $s$,
\begin{equation}
(6.10) \quad \epsilon_e := \begin{cases}
1, & e = b, \\
-1, & e = a,
\end{cases}
\end{equation}
and the second equality in (6.9) follows from (6.8) and the fact $|\phi_c(z)| \sim |z - e|^{3/2}$. Thus, we can define an analytic branch of $(-\phi_c)^{2/3}(z)$ that is positive on $I_e$. Then (6.9) yields that
\begin{equation}
(-\phi_c)^{2/3}(s) = (-2\pi \mu_t (J_{s,c}))^{2/3}, \quad s \in J_e,
\end{equation}
that is, $(-\phi_c)^{2/3}(z)$ is holomorphic across $J_e$. Since $(-\phi_c)^{2/3}(z)$ has a simple zero at $e$, it is conformal in some region around $e$. It will be clear from the choice of $\rho(t)$ in Section 6.4 that this region contains $U_e$. Thus, we get that $(-\phi_c)^{2/3}(z)$ maps $U_e$ conformally onto some neighborhood of the origin and satisfies
\begin{equation}
(6.11) \quad \begin{cases}
(-\phi_c)^{2/3}(J_e) \subset (\infty, 0), \\
(-\phi_c)^{2/3}(I_e) \subset (0, \infty).
\end{cases}
\end{equation}
Furthermore, if we define $(-\phi_c)^{1/6}(z)$ to be holomorphic in $U_e \setminus J_e$ and positive on $I_e$, then
\begin{equation}
(6.12) \quad (-\phi_c)^{1/6}(s) = \epsilon_e i (-\phi_c)^{1/6}(s), \quad s \in J_e.
\end{equation}
6.3. Local analysis at $c$. Assume that $t \in \{ t_{\text{crit}}, e^{2\pi i/3} t_{\text{crit}} \}$. Then either $c = b$ or $c = a$. In any case $c$ is a triple zero of $Q$. Define $\varepsilon_c$ by (6.10). Define $U_c$ by (6.6) with

$$ \rho(t_{\text{cr}}) := \rho(e^{2\pi i/3} t_{\text{cr}}) := 1/3, $$

where again $\delta_c \in (0, 1]$. Let $I_c$ and $J_c$ be as in (6.7). It follows from (3.1) that $\phi_c(z) \sim |z - c|^{5/2}$ as $z \to c$. Since $\phi_c < 0$ on $I_c$ and the angle between $I_c$ and $J_c$ is $3\pi/5$, we can define a branch of $\phi_c^{2/5}$ that is conformal around $c$, in fact, in $U_c$ (see the analysis in the next section) and is negative on $J_c$. That is, $\phi_c^{2/5}$ maps $U_c$ conformally onto some neighborhood of the origin and satisfies

$$ \phi_c^{2/5}(J_c) \subset \{ z : \arg(z) = \varepsilon_c \pi \}, $$

$$ \phi_c^{2/5}(I_c) \subset \{ z : \arg(z) = \varepsilon_c 2\pi/5 \}. $$

Moreover, (6.12) is replaced in this case by

$$ \phi_c^{1/10}(s) = \varepsilon_c \phi_c^{-1/10}(s), \quad s \in J_c. $$

Let now $t \in C_{\text{split}}$. Determining the left and right sides of $\Gamma_t$ by its orientation, set

$$ \varphi(z) := \begin{cases} -\phi_0(z), & z \text{ is to the left of } \Gamma_t, \\ \phi_0(z), & z \text{ is to the right of } \Gamma_t. \end{cases} $$

It follows from (6.3) that $\varphi - \varphi(c)$ is holomorphic across $J_t$, vanishes at $c$, is negative purely imaginary on $\Gamma_t(a,c)$, and positive purely imaginary on $\Gamma_t(c,b)$. Moreover, (3.1) yields that $|\varphi(z) - \varphi(c)| \sim |z - c|^2$ as $z \to c$. Therefore, we can define a branch of $(\varphi - \varphi(c))^{1/2}$ that is conformal around $c$ and satisfies

$$ \varphi(z) := \begin{cases} (\varphi - \varphi(c))^{1/2}(\Gamma_t(a,c)) \subset \{ z : \arg(z) = \pi/4 \}, \\ (\varphi - \varphi(c))^{1/2}(\Gamma_t(c,b)) \subset \{ z : \arg(z) = 3\pi/4 \}. \end{cases} $$

As before, we attach a circular neighborhood to $c$ of the form

$$ U_c := \{ z : |z - c| < \delta_c \rho(t) |a - b| \}, $$

where, as in (6.6), $\rho(t)$ is a function that will be specified in the next section (in particular, it will ensure conformality of $(\varphi - \varphi(c))^{1/2}$ in $U_c$), and $\delta_c \in (0, 1]$. Finally, let us consider the case $t \in C_{\text{orbital}}$, $e \in \{a, b\}$. Define $\phi_e := \phi_e - \phi_e(c)$. Notice that $\phi_e$ has a double zero at $c$ and it is real negative on $\Gamma_t$ around $c$. Hence, we can select a branch of $(-\phi_e)^{1/2}$ that is conformal in $U_c$ of the form (6.18), satisfies

$$ (-\phi_e)^{1/2}(\Gamma_t \cap U_c) \subset \mathbb{R}, $$

and preserves the orientation (positive direction on $\Gamma_t$ is mapped into the positive direction on $\mathbb{R}$). As it will be important latter, let us also observe that $\phi_e(c)$ is purely imaginary.

6.4. Neighborhoods $U_c$. The goal of this section is to specify the function $\rho(t)$ appearing in the definition of the neighborhoods of $U_c$, $e \in \{a, b, c\}$, in (6.6) and (6.18). We would like to show that this function can be chosen in such a fashion that the corresponding map is conformal in $U_c$ and the image of $U_c$ under this map contains a disk

$$ \{ z : |z| < \delta_c \tilde{\rho}(t)/32 \}, $$

where $\tilde{\rho}(t)$ is a continuous positive function in $\overline{O_{\text{one-cut}}} \setminus \{ t_{\text{cr}}, e^{2\pi i/3} t_{\text{cr}} \}$ that is separated from zero when $t \to \infty$, and the constant $1/32$ is introduced for convenience only.

The main tool in showing that the above requirement can be met is the Basic Structure Theorem, see [28, Theorem 3.5]. It states in particular that the function $\phi_e(z)$, defined in (6.2), is conformal in each connected component of the complement of the joint critical graph (critical and critical orthogonal) of $\varphi_t$ (see Figures 4 and 5 for the possible configurations of this graph). Recall that $\Re \phi_e(z)$ is constant on the critical trajectories and $\Im \phi_e(z)$ is constant on the critical orthogonal trajectories. Therefore, each connected component of the complement of the joint critical graph is mapped by $\phi_e(z)$ into a quadrant, semi-infinite strip, or a rectangle, see Figure 12. Moreover, if two such regions share a side that is the image of the same part of the joint critical graph, then $\phi_e(z)$ extends conformally through this side. As $|\phi_e(b)| = |\phi_e(a)| = 2\pi$ for any $t$, the inverse of the restriction of $\phi_e$ to any
connected component is conformal in the intersection of the image of the component under \( \phi_c(z) \) and any disk of radius at most \( \min \{ 2\pi, |\phi_c(c)| \} \). In particular, the inverse of \( (-\phi_c)^{2/3} \) is conformal in a disk
\[
\{ z : |z| < \tilde{\rho}_c(t)/2 \}, \quad \tilde{\rho}_c(t) := \left( \min \{ 2\pi, |\phi_c(c)| \} \right)^{2/3}.
\]

It follows from a direct computation and (3.7) that
\[
(-\phi_c)^{2/3} \left( \frac{2}{3} \right) (c) = \frac{\sqrt{96}}{|a-b|} \left( 1 + \frac{\kappa_c}{\sqrt{2x_3/2}} \right)^{2/3}
\]
for any \( t \neq \text{tct}, e^{2\pi i/3}\text{tct} \). Koebe’s Quarter Theorem then yields that \((-\phi_c)^{2/3}\) is conformal in any disk (6.6) with
\[
\rho(t) := \min \left\{ \frac{1}{3} \tilde{\rho}(t), \frac{1}{3} \tilde{\rho}(t), \tilde{\rho}(t) \right\}, \quad \tilde{\rho}(t) := \min \left\{ \tilde{\rho}_a(t), \tilde{\rho}_b(t) \right\},
\]
which, together with Koebe’s Quarter Theorem used once more, implies that (6.20) indeed takes place (we bound \( \rho(t) \) by \( 1/3 \) for convenience only). Notice that the rate of decay to zero of \( \tilde{\rho}(t) \) as \( t \to \{ \text{tct}, e^{2\pi i/3}\text{tct} \} \) can be deduced from (5.7) as \( |\phi_c(c)| = |I_x(-x)| \) and the fact that an analogous formula holds for \( |\phi_a(c)| \).

It is not hard to see that the above argument can be applied to the conformal map around \( c \) when \( t \in \text{Csplit} \cup \text{Cbirth} \) to show that the conclusion (6.20) still holds for \( U_c \) as in (6.18) with \( \tilde{\rho}(t) \) now defined as \( \min \{ \tilde{\rho}_a(t), \tilde{\rho}_b(t), \tilde{\rho}_c(t) \} \), where
\[
\tilde{\rho}_c^2(t) = \begin{cases} 
\min \{ |\phi_c(a)|, |\phi_c(b)| \}, & t \in \text{Cbirth}, \\
\min \{ |\phi(a) - \varphi(c)|, |\varphi(b) - \varphi(c)| \}, & t \in \text{Csplit}.
\end{cases}
\]

6.5. Functions \( D(z; t), A(z; t), \) and \( B(z; t) \). Let \( D(z; t) \) be given by (4.12). As in (5.5) we can compute that
\[
\sqrt{(z-a)(z-b)} = z - x + \frac{1}{xz} + \frac{1}{z^2} + \frac{1}{z^3} \left( x - \frac{1}{2x^2} \right) + \frac{1}{z^2} \left( x^2 - \frac{3}{2x} \right) + O \left( \frac{1}{z^3} \right)
\]
and therefore
\[
(z^2 + zx - 2t) \sqrt{(z-a)(z-b)} = z^3 - 3zt + 2x^3 + \frac{3}{2x^2} + O \left( \frac{1}{z^3} \right),
\]
from which the analyticity and normalization at infinity follow. The equality in (4.13) is a trivial consequence of the behavior of the square root along the branch cut.
Define $F(z)$ as in (4.16). Since $\left(\frac{s-b}{s-a}\right)^{1/4} = i \left(\frac{s-b}{s-a}\right)^{1/4}$ for $s \in J_t$, it holds that

\[(6.23) \quad A \left( s; t \right) = \pm B \left( s; t \right) \Rightarrow F_+ \left( s \right) F_- \left( s \right) \equiv 1, \quad s \in J_t.\]

Notice also that neither $A$ nor $B$ is equal to zero in $\mathbb{C}$. Indeed, denote by $\mathcal{R}$ the Riemann surface realized as two copies of $\overline{\mathbb{C}} \setminus J_t$ glued to each other crosswise along $J_t$. Lift $A^2$ to one of the sheets of $\mathcal{R}$ (a copy of $\overline{\mathbb{C}} \setminus J_t$) and $B^2$ to another. It follows from (6.23) that thus defined function is rational on $\mathcal{R}$. As it only has two poles (at the places that project to $a$ and $b$), it has exactly two zeros. Since $B^2$ has a double zero at infinity, the claim follows.

We further deduce from the previous paragraph that $F(z)$ is non-vanishing and finite in $\mathbb{C} \setminus J_t$ and has a simple pole at infinity. Hence, it follows from (6.23) that by lifting $F$ to one of the sheets of $\mathcal{R}$ and $F^{-1}$ to another, we construct a rational function with a single pole and a single zero, both projecting to the point at infinity. Clearly, a similar lift of the right-hand side of (4.16) and its reciprocal to $\mathcal{R}$ produces a rational function with the same properties. The normalization at infinity then gives (4.16). Observe also that the above argument applied to the ratio of the right- and left-hand sides of (4.14) together with (4.13), (6.5), (6.23), and the normalization at infinity implies the validity of (4.14) as well. For further use, let us also record several estimates. By the very definition of $U_a$ in (6.6) and (6.13), we have that

\[(6.24) \quad \frac{2}{3\delta_a \rho(t)} \leq \frac{1}{\delta_a \rho(t)} - 1 \leq \left| \frac{s-b}{s-a} \right| \leq 1 + \frac{1}{\delta_a \rho(t)} \leq \frac{4}{3\delta_a \rho(t)}, \quad s \in \partial U_a,\]

where we used the estimate $\delta_a \rho(t) \leq 1/3$ and our convention (6.13). Since an analogous bound holds on $\partial U_b$, we get that

\[(6.25) \quad |A(z; t)|, |B(z; t)| \leq \left( \min \{\delta_a, \delta_b\} \rho(t) \right)^{-1/4}, \quad z \in \overline{\mathbb{C}} \setminus (U_a \cup U_b),\]

where the bound extends outside of $U_a \cup U_b$ by the maximum modulus principle applied on the lift $\partial U_a \cup \partial U_b$ to $\mathcal{R}$ to the rational function on $\mathcal{R}$ comprised of the lifts of $A^2$ and $B^2$. Similarly, we deduce from (6.24) that

\[(6.26) \quad |A(s; t)|^{-1}, |B(s; t)|^{-1} \leq 8 \left( \max \{\delta_a, \delta_b\} \rho(t) \right)^{1/4}, \quad s \in \partial U_a \cup \partial U_b,\]

and therefore it follows from the very definition of $F(z)$ as the left-hand side of (4.16) that

\[(6.27) \quad |F^{\pm 1}(z)| \leq 8, \quad z \in \overline{U_a} \cup \overline{U_b},\]

independently of $t$, where we apply the argument with $\delta_a = \delta_b = 1$ on the corresponding $\partial U_a \cup \partial U_b$ and then extend the bound inside by the maximum modulus principle applied on $\mathcal{R}$. In fact, it also holds that

\[(6.28) \quad |F^{-1}(z)| = \mathcal{O}(1)\]

uniformly for $z \in \overline{\mathbb{C}} \setminus J_t$ and $t \in \overline{\mathcal{O}_{\text{one-cut}}}$. Indeed, by the maximum modulus principle and the analyticity of $F^{-1}(z)$ in $\overline{\mathbb{C}} \setminus J_t$, we only need to prove (6.28) for the traces $F^{\pm 1}(s)$, $s \in J_t$. Moreover, the compactness argument shows that it is sufficient to consider only $|t|$ large. As explained in Section 6.4, in such situations the inverse of $(-\phi_e)^{2/3}$, $e \in \{a, b\}$, is conformal in the disk of radius $(2\pi)^{2/3}$. Moreover, $(-\phi_a)^{2/3}(b)$ or $(-\phi_b)^{2/3}(a)$, depending on whether $e = a$ or $e = b$, belongs to the boundary of this disk. Hence,

\[J_t \subseteq \left( (-\phi_a)^{2/3} \right)^{-1}(U) \cup \left( (-\phi_b)^{2/3} \right)^{-1}(U), \quad U := \left\{ z : \ |z| < 2(2\pi)^{2/3}/3 \right\}.\]

Then it follows from Koebe’s distortion theorem and (6.21) that

\[|s - e| \leq \text{const}|a - b|, \quad s \in J_t \cap \left( (-\phi_e)^{2/3} \right)^{-1}(U),\]

for some absolute constant. Therefore, $|s - e| \leq \text{const}|a - b|$ for all $s \in J_t$ and $e \in \{a, b\}$. This estimate and the explicit expression

\[F^{-1}(z) = \frac{2}{b-a} \left( z - \frac{b+a}{2} - \sqrt{(z-a)(z-b)} \right)\]

immediately imply the desired bound on $J_t$. 

7. Asymptotic Analysis

7.1. Initial Riemann-Hilbert problem. In what follows, it will be convenient to set

\[ I := \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \sigma_1 := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \text{and} \quad \sigma_3 := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \]

We are seeking solutions of the following sequence of Riemann-Hilbert problems for $2 \times 2$ matrix-valued functions (RHP-$Y$):

(a) $Y$ is analytic in $\mathbb{C} \setminus \Gamma$ and $\lim_{z \to \infty} Y(z)z^{-n}Y^* = I$;

(b) $Y$ has continuous traces on $\Gamma \setminus \{a, b, c\}$ that satisfy

\[ Y_+(s) = Y_-(s) \begin{pmatrix} 1 & e^{-NV(s,t)} \\ 0 & 1 \end{pmatrix}. \]

The connection of RHP-$Y$ to orthogonal polynomials was first demonstrated by Fokas, Its, and Kitaev in [24] and lies in the following. If the solution of RHP-$Y$ exists, then it is necessarily of the form

\[ Y(z) = \begin{pmatrix} P_n(z) & (CP_n e^{-NV}) (z) \\ -\frac{2\pi i}{h_{n-1}} P_{n-1}(z) & -\frac{2\pi i}{h_{n-1}} (CP_{n-1} e^{-NV}) (z) \end{pmatrix}, \]

where $P_n$ is the polynomial satisfying orthogonality relations (1.26), $h_k$ are constants defined by (1.28), and $Cf$ is the Cauchy transform of a function $f$ given on $\Gamma_t$, i.e.,

\[ (Cf)(z) = \frac{1}{2\pi i} \int_{\Gamma_t} \frac{f(s)}{s - z} ds. \]

Below, we show the solvability of RHP-$Y$ for all $|n - N| \leq N_0$ and $N$ large enough following the framework of the steepest descent analysis introduced by Dieff and Zhou [19]. The latter lies in a series of transformations which reduce the initial problem to a problem with jumps asymptotically close to the identity.

7.2. Renormalized Riemann-Hilbert problem. Suppose that $Y$ is a solution of RHP-$Y$. Put

\[ T := e^{N\ell'_t/2} \left( \frac{4}{b - a} \right)^{(n-N)\sigma_3} Y(z)e^{-N\left(g + \ell'_t/2\right)\sigma_3} F^{N-n}\sigma_3, \]

where the function $g$ is defined by (4.10), $\ell'_t$ is introduced in (6.1), and $F = -iA/B$ is a function from (4.16). Then

\[ T_+ = T_- \begin{pmatrix} (F_+^* / F_-)^{N-n} e^{-N(g_+ - g_-)} & (F_+^* / F_-)^{N-n} e^{-N(g_+ + g_- + V'_t)} \\ 0 & (F_- / F_+)^{N-n} e^{-N(g_+ - g_-)} \end{pmatrix}, \]

on $\Gamma_t$, and therefore we deduce from (4.11), (4.16), (6.4), (6.5), and (6.23) that $T$ solves RHP-$T$:

(a) $T$ is analytic in $\mathbb{C} \setminus \Gamma_t$ and $\lim_{z \to \infty} T(z) = I$;

(b) $T$ has continuous traces on $\Gamma_t \setminus \{a, b, c\}$ that satisfy

\[ T_+ = T_- \begin{cases} \begin{pmatrix} 1 & F^{2(n-N)}e^{N\phi_+} \\ 0 & 1 \end{pmatrix}, & \text{on } \Gamma_t(b, e^{\pi i/3}) \\
\begin{pmatrix} F^{2(N-n)}e^{-N\phi_-} & 1 \\ 0 & F^{2(n-N)}e^{-N\phi_-} \end{pmatrix}, & \text{on } \Gamma_t(a, b), \\
\begin{pmatrix} 1 & F^{2(n-N)}e^{N\phi_-} \\ 0 & 1 \end{pmatrix}, & \text{on } \Gamma_t(e^{\pi i}a, a). \end{cases} \]

Clearly, if RHP-$T$ is solvable and $T$ is the solution, then by inverting (7.2) one obtains a matrix $Y$ that solves RHP-$Y$. 

TOPOLOGICAL EXPANSION IN THE COMPLEX CUBIC LOG-GAS MODEL. ONE-CUT CASE 23
7.3. Lens opening. As usual in the steepest descent analysis of matrix Riemann-Hilbert problems for orthogonal polynomials, the next step is based on the identity
\[
\begin{pmatrix} a_+ & 1 \\ 0 & a_- \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ a_- & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ a_+ & 1 \end{pmatrix}, \quad a_+ a_- \equiv 1,
\]
which is applicable by (6.3) and (6.23). To carry it out, we shall introduce two additional arcs. Denote by \( J_{\pm} \) smooth homotopic deformations of \( J_t \) within the region \( \Re (\phi_b(z)) > 0 \) such that \( J_+ \) lies to the left and \( J_- \) to the right of \( J_t \), see Figure 13. Moreover, we shall

![Figure 13](image)

**Figure 13.** The thick arcs represent \( \Gamma_t \) and thinner arcs represent \( J_{\pm} \). Shaded region is the set where \( \Re (\phi_b(z)) < 0 \).

fix the way these arcs emanate from \( e \in \{a,b\} \). Namely, let \( U_e \) be a disk centered at \( e \) as described in Sections 6.2–6.4. Assume first that we are in a generic situation when \( e \neq c \). Then we require that
\[
\text{(7.3)} \quad \arg\left( (-\phi_e)^{2/3}(z) \right) = \pm \epsilon_e (2\pi/3), \quad z \in U_e \cap J_{\pm},
\]
where \( \epsilon_e \) is defined by (6.10). The latter is always possible due to (6.11). Suppose now that \( e = c \in \{a,b\} \). Then we require that
\[
\text{(7.4)} \quad \arg\left( \phi_c^{2/5}(z) \right) = \pm \epsilon_c (4\pi/5), \quad z \in U_c \cap J_{\pm},
\]
where \( \epsilon_c \) is still defined by (6.10) and such a choice is possible according to (6.14). In addition, when \( c \in J_t \setminus \{a,b\} \), it necessarily holds that \( J_- \) touches \( J_t \) at \( c \). We shall choose \( J_- \) around \( c \) so that
\[
\text{(7.5)} \quad (\varphi - \varphi(c))^{1/2}(U_c \cap J_-) \subset \mathbb{R},
\]
where \( \varphi \) is defined by (6.16) and such a choice is possible due to (6.17).

Denote by \( O_{\pm} \) the open sets delimited by \( J_{\pm} \) and \( J_t \). Set
\[
\text{(7.6)} \quad S(z) := T(z) \begin{cases} 1 \\ \mp F^{2/(N-n)}(z) e^{-N\phi_b(z)} \end{cases}, \quad z \in O_{\pm},
\]
otherwise.

Then, if \( T \) solves RHP-T, \( S \) solves RHP-S:

(a) \( S \) is analytic in \( \mathbb{C} \setminus (\Gamma_t \cup J_+ \cup J_-) \) and \( \lim_{z \to \infty} S(z) = I \);
(b) \( S \) has continuous traces on \( \Gamma_t \setminus \{a,b,c\} \) that satisfy RHP-T(b) on \( \Gamma_t(e^{\pi i} \infty, a) \) and \( \Gamma_t(b, e^{\pi i/3} \infty) \), as well as
\[
S_+(s) = S_-(s) \begin{cases} 0 \\ -1 \end{cases}, \quad s \in J_t,
\]
\[
\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad s \in J_{\pm}.
\]
As before, since transformation (7.6) is invertible, a solution of RHP-S yields a solution of RHP-T.
7.4. Model solution. The model Riemann-Hilbert problem RHP-\(M\) is obtained from RHP-\(S\) by removing from the jump matrices in RHP-\(S\)(b) the quantities that are asymptotically zero. Thus, we are seeking the solution of RHP-\(M\):

(a) \(M\) is analytic in \(\mathbb{C} \setminus J_t\) and \(M(\infty) = I\);
(b) \(M\) has continuous traces on \(\Gamma_t(a,b)\) that satisfy

\[
M_+(s) = M_-(s) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad s \in \Gamma_t(a,b).
\]

Using (6.23), one can easily verify that RHP-\(M\) is solved by

\[
M(z) := \begin{pmatrix} A(z;t) & -B(z;t) \\ B(z;t) & A(z;t) \end{pmatrix},
\]

where \(A(z;t)\) and \(B(z;t)\) are given by (4.15). Observe also that \(\text{det}(M) \equiv 1\) in \(\mathbb{C}\).

7.5. Local parametrices. The jumps discarded in RHP-\(M\) are not uniformly close to the identity around \(e \in \{a, b, c\}\) (the point \(e = c\) is included when \(t \in \partial\Omega_{\text{one-cut}}\)). The goal of this section is to solve RHP-\(S\) within the disks \(U_e\) introduced in Sections 6.2–6.4 with a certain matching condition on \(\partial U_e\). More precisely, given \(e \in \{a, b, c\}\), we are looking for a matrix-valued function \(P_e\) that solves RHP-\(P_e\):

(a) \(P_e\) has the same analyticity properties as \(S\) restricted to \(U_e\), see RHP-\(S\)(a);
(b) \(P_e\) satisfies the same jump relations as \(S\) restricted to \(U_e\), see RHP-\(S\)(b);
(c) \(P_e = M(I + \mathcal{O}(N^{-\alpha_e}))\) holds uniformly on \(\partial U_e\) as \(N \to \infty\) for some \(\alpha_e > 0\).

7.5.1. Parametrix \(P_e\) around \(e \in \{a, b\}, e \neq c\). Let \(U_e, J_e\), and \(I_e\) be as in (6.7). In this section we are looking for a matrix function \(P_e\) that is holomorphic in \(U_e \setminus (\Gamma_t \cup J_+ \cup J_-)\), fulfills RHP-\(P_e\)(c), and whose traces satisfy

\[
P_{e+}(s) = P_{e-}(s) \begin{cases} 
\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, & s \in J_e, \\
\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, & s \in J_\pm \cap U_e, \\
\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, & s \in I_e,
\end{cases}
\]

Notice that we replaced \(\phi_s\) by \(\phi_s\), as compared to RHP-\(S\)(b). Such a substitution is possible due to the first relation in (6.3).

Let \(A\) be the Airy matrix [15, 16]. That is, it is analytic in \(\mathbb{C} \setminus ((-\infty, \infty) \cup L_- \cup L_+)\), \(L_\pm := \{z : \arg(z) = \pm 2\pi/3\}\), and satisfies

\[
A_+(s) = A_-(s) \begin{cases} 
\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, & s \in (-\infty, 0), \\
\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, & s \in L_\pm, \\
\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, & s \in (0, \infty),
\end{cases}
\]

where the real line is oriented from \(-\infty\) to \(\infty\) and the rays \(L_\pm\) are oriented towards the origin. It is known that \(A\) has the following asymptotic expansion at infinity:

\[
A(\zeta)e^{\xi \zeta^{3/2} \sigma_3} \sim \zeta^{-\sigma_3/4} \sqrt{2} \sum_{k=0}^\infty \begin{pmatrix} s_k & 0 \\ 0 & t_k \end{pmatrix} \begin{pmatrix} (-1)^k & i^{1/3} \\ -i^{1/3} & 1 \end{pmatrix} \left(2^\zeta \zeta^{3/2}\right)^{-k},
\]

where the expansion holds uniformly in \(\mathbb{C} \setminus ((-\infty, \infty) \cup L_- \cup L_+)\), and

\[
s_0 = t_0 = 1, \quad s_k = \frac{\Gamma(3k + 1/2)}{54^k k! \Gamma(k + 1/2)}, \quad t_k = -\frac{6k + 1}{6k - 1} s_k, \quad k \geq 1.
\]

Set \(A_b := A\) and \(A_a := \sigma_3 A \sigma_3\). It can be easily checked that \(\sigma_3 A \sigma_3\) has the same jumps as \(A\) only with the reversed orientation of the real line and the rays \(L_\pm\). Moreover,
one needs to replace each occurrence of $i$ by $-i$ in (7.9) when describing the asymptotic expansion $\sigma_3 A\sigma_3$. Then (6.3), (6.11), and (7.3) yield that the matrix function

$$P_e(z) = E_e(z)A_e \left( \left[-(3/4)N\phi_e(z)\right]^{2/3} e^{-N\phi_e(z)\sigma_3/2} F(N-n)\sigma_3(z) \right)$$

satisfies $\text{RHP-}P_e$ (a) and $\text{RHP-}P_e$ (b) for any matrix function $E_e$ holomorphic in $U_e$. Thus, we only need to choose $E_e$ so that $\text{RHP-}P_e(c)$ is fulfilled. Choose

$$E_e(z) := M(z) F(n-N)\sigma_3(z) \left( \begin{array}{ccc} \frac{1}{1-\varepsilon_3 i} & \varepsilon_3 i 1 \end{array} \right) \left[ -(3/4)N\phi_e(z) \right]^{\sigma_3/6} \sqrt{2}$$

whose analyticity in $U_e$ follows $\text{RHP-M}$ (b), (6.23), and (6.12) with $\varepsilon_3$ given by (6.10). Then we deduce from (7.9) and (7.10) that

$$P_e(z) \sim M(z) F(n-N)\sigma_3(z) \left( I + N^{-\alpha} \sum_{k=0}^{\infty} P_{e,k}(z) N^{-k} \right) F(n-N)\sigma_3(z),$$

where the expansion inside the parenthesis holds uniformly on $\partial U_e$ and locally uniformly for $t \in \mathcal{O}_{\text{one-cut}} \setminus \{t_\alpha, e^{2\pi i/3} t_\alpha\}$ by (6.20), the parameter $\alpha = 1$, and

$$P_{e,k-1}(z) = \left( \begin{array}{ccc} 1 & -\varepsilon_3 i \ 0 & 1 \end{array} \right) \left( \begin{array}{ccc} s_k & 0 
 \varepsilon_3 i & 1 \end{array} \right) \left( \frac{(-1)^k}{\varepsilon_3(-1)^k i} \right) \left( \frac{\phi_e(z)}{2} \right)^{-k}, \quad k \geq 1.$$

7.5.2. Parametrix $P_e$ around $c \in \{a,b\}$. The local problem at $c = c$ is formulated exactly as before with the jumps as in (7.8). However, the above solution does not apply because $\phi_e(z)^{2/3}$ is no longer conformal (we shall replace it by $\phi_e^{2/5}$) and the arcs $I_e$ and $J_e$ no longer form an angle $\pi$ at $c$ (it is $3\pi/5$).

As in the previous subsection, we shall need an auxiliary matrix-valued function. This time it depends on two parameters: $\alpha, \lambda \in \mathbb{C}$, and solves the following Riemann-Hilbert problem (RHP-Ψ):

(a) $\Psi_\alpha$ is a holomorphic matrix function in $\mathbb{C} \setminus \left( (-\infty, 0) \cup L_1 - \cup L_1 + \cup L_2 - \cup L_2 + \right)$, where $L_{\pm} := \\{ z : \arg(z) = \pm 2k\pi/5 \}$, the rays $(-\infty, 0)$ and $L_{\pm}$ are oriented towards the origin while $L_{-\pm}$ are oriented away from the origin;

(b) $\Psi_\alpha$ has continuous traces on $(-\infty, 0) \cup L_1 - \cup L_1 + \cup L_2 - \cup L_2 +$ that satisfy

$$\Psi_{\alpha+}(s; \lambda) = \Psi_{\alpha-}(s; \lambda) \begin{cases} 
0 & s \in (-\infty, 0), \\
1 & s \in L_{\pm}, \\
1 - \alpha & s \in L_1 +, \\
1 & s \in L_{1-}, \end{cases}$$

where $\alpha \in \mathbb{C}$ satisfies

$$\Psi_\alpha(\zeta; \lambda) = \left( \begin{array}{ccc} \zeta^{-\sigma_3/4} \ 1 \ -i \\
1 & \zeta^{-1/2} \ \zeta \end{array} \right) e^{\left( \frac{2\zeta^{1/2} + \lambda(1/2)\sigma_3}{\sqrt{2}} \right)^\theta}$$

uniformly in $\mathbb{C} \setminus \left( (-\infty, 0) \cup L_1 - \cup L_1 + \cup L_2 - \cup L_2 + \right)$. $\text{RHP-Ψ}$ characterizes $\text{trouquée}$ solutions of Painlevé I equation [29]. That is, $\Psi_\alpha(\zeta; \lambda)$ satisfies the following system of linear ODEs:

$$\begin{cases} 
\partial_\zeta(\Psi_\alpha(\zeta; \lambda)) \Psi_\alpha(\zeta; \lambda)^{-1} = \\
\partial_\lambda(\Psi_\alpha(\zeta; \lambda)) \Psi_\alpha(\zeta; \lambda)^{-1} = \\
\begin{pmatrix} -\partial_\lambda y_0 & 2\zeta^2 + 2\zeta y_0 + \lambda + 2y_0^2 \\\n2\zeta - 2y_0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & \zeta + 2y_0 \\
1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & \zeta + 2y_0 \\
1 & 0 \end{pmatrix}
\end{cases}$$

with the functions $y_0(\lambda)$ forming a one parameter family of solutions to $y''(\lambda) = 6y^2(\lambda) + \lambda$ and satisfying $y_0(\lambda) = \sqrt{-\lambda/6} \left(1 + O\left((\lambda - \lambda)^{-5/2}\right)\right)$ as $|\lambda| \to \infty$, $|\arg(\lambda) - \pi| < 2\pi/5$, where the parameter $\alpha$ appears when describing the more detailed asymptotics of $y_0$. In particular,
uniformly in the upper and lower half-planes by [18, Eq. (7.12.1) or Eq. (12.9.1)]. Thus, we is a tronqu´e solution as designated by Boutroux [10]. Moreover, the functions \( y_0(\lambda) \) and \( y_1(\lambda) \) are known to be tritronqu´ee solutions as they are asymptotically pole free in sectors \( |\arg(\lambda) - \pi/2| < 2\pi/5 \) for \(|\lambda| \) large, and therefore it is known that \( \text{RHP-} \Psi \) is solvable if and only if \( \lambda \) is not a pole of the corresponding solution \( \Psi_0 \) [20, Section 4.6]. It is also known that tritronqu´ee solutions are pole free in a disk around the origin [11, Theorem 1]. Hence, the matrices \( \Psi_0(\cdot; 0) \) and \( \Psi_1(\cdot; 0) \) exist and have the properties described by \( \text{RHP-} \Psi \).

Set \( B_b := \Psi_0(\cdot; 0) \) and \( B_c := \sigma_3 \Psi_1(\cdot; 0) \sigma_3 \). As before, one can check that \( \sigma_3 \Psi_0 \sigma_3 \) has the same jumps as \( \Psi_0 \), only with the reversed orientation of the rays. Moreover, one needs to replace the anti-diagonal elements in \( \text{RHP-} \Psi \) by their negatives when describing the behavior of \( \sigma_3 \Psi_0 \sigma_3 \) at infinity. Then (6.3), (6.14), and (7.4) yield that the matrix function

\[
P_c(z) = \begin{pmatrix} 1 & 0 \\ 0 & e_c \end{pmatrix} B_c \begin{pmatrix} (5/8)N\phi_c(z) \end{pmatrix}^{2/5} e^{-N\phi_c(z)\sigma_3/2} F^{(n-n)\sigma_3}(z)
\]

satisfies \( \text{RHP-} P_c \) (a) and \( \text{RHP-} P_c \) (b) for any matrix function \( E_c \) holomorphic in \( U_c \). Thus, we only need to choose \( E_c \) so that \( \text{RHP-} P_c \) (c) is fulfilled. Choose

\[
E_c(z) := M(z) F^{(n-n)\sigma_3}(z) \begin{pmatrix} 1 \varepsilon_c \\ -1 \end{pmatrix} \begin{pmatrix} (5/8)N\phi_c(z) \end{pmatrix}^{\sigma_3/10} \sqrt{2},
\]

whose analyticity in \( U_c \) follows (6.15), (6.23), and \( \text{RHP-} M \) (b). It can be readily verified that (7.14) satisfies (7.11) uniformly on \( \partial U_c \) with \( \alpha_c = 1/5 \) and

\[
P_{c,k}(z) = \begin{pmatrix} 1 & 0 \\ 0 & e_c \end{pmatrix} \Psi_k \begin{pmatrix} 1 & 0 \\ 0 & e_c \end{pmatrix} \begin{pmatrix} 5/8 \phi_c(z) \end{pmatrix}^{\sigma_3/5}
\]

where the \( O(\zeta^{-1/2}) \sim \sum_{k=1}^{\infty} \Psi_k \zeta^{-k/2} \) is the error term from \( \text{RHP-} \Psi \) (c) and the matrices \( \Psi_k \) can be found recursively using (7.13).

7.5.3. Parametrix \( P_c \) around \( c \in \Gamma_1(a,b) \). Recall that \( U_c \) is given by (6.18). We always can adjust the constant \( \delta_c \) so that \( J_+ \cap U_c = \emptyset \). In this case \( P_c \) is a holomorphic matrix in \( U_c \setminus (J_+ \cup J_-) \) that fulfills \( \text{RHP-} P_c \) (c) and whose traces satisfy

\[
P_{c,+}(s) = P_{c,-}(s) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad s \in (U_c \cap J_+) \setminus \{c\},
\]

\[
P_{c,-}(s) = P_{c,+}(s) \begin{pmatrix} 1 \\ 0 \end{pmatrix} e^{-N\phi_c(s)}, \quad s \in (U_c \cap J_-) \setminus \{c\}.
\]

Let \( C \) be the following matrix-valued function:

\[
C(\zeta) := \begin{pmatrix} e^{\zeta^2} & 0 \\ b(\zeta) & e^{-\zeta^2} \end{pmatrix}, \quad b(\zeta) := \frac{1}{2} e^{-\zeta^2} \left\{ \begin{array}{cl} \text{erfc}(-i\sqrt{2} \zeta), & \text{Im}(\zeta) > 0, \\
\text{erfci}(i\sqrt{2} \zeta), & \text{Im}(\zeta) < 0. \end{array} \right.
\]

Equivalently, we could have defined \( b(\zeta) \) as \( \pm(2\pi)^{-1/2} U(1/2; \mp 2i\zeta), \pm\text{Im}(\zeta) > 0, \) see [18, Eq. (12.7.5)], where \( U(a;z) \) is a parabolic cylinder function solving [18, Eq. (12.2.2)]. Observe that

\[
b_+(x) - b_-(x) = \frac{1}{2} e^{-x^2} \left\{ \text{erfc}(-i\sqrt{2} x) + \text{erfci}(i\sqrt{2} x) \right\} = e^{-x^2},
\]

for \( x \in \mathbb{R} \) and therefore

\[
C_+ = C_- \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \quad \text{on} \quad \mathbb{R}.
\]

Moreover, since \( \text{Re}(-i\zeta) > 0 \) when \( \text{Im}(\zeta) > 0 \) and \( \text{Re}(i\zeta) > 0 \) when \( \text{Im}(\zeta) < 0 \), it holds that

\[
b(\zeta) \sim \frac{i e^{\zeta^2}}{\sqrt{2\pi}} \sum_{k=0}^{\infty} \frac{\Gamma(k + 1/2)}{2^{k+1} \Gamma(1/2)} \zeta^{-(2k+1)} =: e^{\zeta^2} \sum_{k=0}^{\infty} b_k \zeta^{-(2k+1)}
\]

uniformly in the upper and lower half-planes by [18, Eq. (7.12.1) or Eq. (12.9.1)]. Thus, we deduce that

\[
C(\zeta) = \begin{pmatrix} 1 & 0 \\ e^{-\zeta^2} b(\zeta) & 1 \end{pmatrix} e^{\zeta^2 \sigma_3} \sim \left( I + \sum_{k=0}^{\infty} \begin{pmatrix} 0 & 0 \\ b_k & 0 \end{pmatrix} \zeta^{-(2k+1)} \right) e^{\zeta^2 \sigma_3} \quad \text{as} \quad \zeta \to \infty.
\]
where the expansion is uniform in the lower and upper half-planes. Set

\[ J(z) := \begin{cases} 
0 & , \quad z \in U_c^+ \\
1 & , \quad z \in U_c^- 
\end{cases} \]

where \( U_c^+ \) is the part of \( U_c \) that lies to the left of \( J_t \) and \( U_c^- \) that lies to the right of it. We claim that RHP-\( P \) is solved by

\[ P_c(z) = M(z)F^{(n-N)}(z)e^{N\varphi(c)\sigma_3/2}C \left( \sqrt{N/2} [\varphi - \varphi(c)]^{1/2}(z) \right) \times 
J^{-1}(z)e^{-N\phi_b(z)\sigma_3/2}F^{(N-n)\sigma_3}(z). \]

Indeed, RHP-\( P \)(a) is satisfied due to the choice of the branch of \((\varphi - \varphi(c))^{1/2}\), see (6.17), and the choice of \( J_t \), see (7.5). Further, since \( J = I \) in \( U_c^- \), analyticity of \( M, \phi_b, \) and \( F \) across \( J \backslash \{ c \} \) as well as (7.5) and (7.18) imply that \( P_c \) has the jump there as in (7.16).

Moreover, observe that

\[ M(z)F^{(n-N)}(z)e^{N\varphi(c)\sigma_3/2}C \left( \sqrt{N/2} [\varphi - \varphi(c)]^{1/2}(z) \right) \]

are analytic across \( J_t \) by RHP-M (b), (6.23), and the choice of \( J \). Hence, since \( \phi_{b_1} + \phi_{b_2} = 0 \) on \( J_t \) by (6.3), it follows from the definition of \( J \) that \( P_c \) has the jumps across \( J_t \) as in (7.16). That is, RHP-\( P \)(b) is fulfilled as well. Finally, we get from (6.16), (6.20), and (7.19) that (7.20) satisfies (7.11) uniformly on \( \partial U_c \) and locally uniformly on \( C_{\text{split}} \) with \( \alpha_e = 1/2 \) and \( F_{c,k} \) given by

\[ \frac{2^{k+1/2} e^{-N\varphi(c)}}{(\varphi(z) - \varphi(c))^{1/2}} \begin{pmatrix} 0 & -b_k \\
0 & 0 \end{pmatrix} \quad \text{and} \quad \frac{2^{k+1/2} e^{-N\varphi(c)}}{(\varphi(z) - \varphi(c))^{1/2}} \begin{pmatrix} 0 & 0 \\
b_k & 0 \end{pmatrix} \]

in \( U_c^+ \) and \( U_c^- \), respectively (recall also that \(|e^{\varphi(c)}| = 1|\)).

7.5.4. Parametrix \( P_e \) around \( c \in \Gamma_t(e^{\pi i} \infty, a) \cup \Gamma_t(b, e^{\pi i/3} \infty) \). Put \( e = a \) if \( c \in \Gamma_t(e^{\pi i} \infty, a) \) and \( e = b \) if \( c \in \Gamma_t(b, e^{\pi i/3} \infty) \). We are seeking a matrix function holomorphic in \( U_c \backslash \Gamma_t \) that fulfills RHP-\( P_e \)(c) and whose traces satisfy

\[ P_{c+}(s) = P_{c-}(s) \begin{pmatrix} 1 & F^{2(n-N)}(s)e^{N\phi_c(s)} \\
0 & 1 \end{pmatrix}, \quad s \in \Gamma_t \cap U_c. \]

The Riemann-Hilbert problem RHP-\( P_e \) is solved by

\[ P_e(z) = M(z)F^{(n-N)}(z)e^{N\phi_c(z)\sigma_3/2}C \left( \left[ 1 - \frac{(N/2)\phi_c(z)}{\varphi - \varphi(c)} \right]^{1/2} \right) \sigma_1 \times 
C^{(N-n)\sigma_3}(z), \]

where \( C \) is defined by (7.17) and \(-\phi_c^{1/2}\) is the branch chosen in (6.19). Indeed, it can be readily verified using (7.18) that

\[ (\sigma_1 C \sigma_1)_+ = (\sigma_1 C \sigma_1)_- \begin{pmatrix} 1 & 1 \\
0 & 1 \end{pmatrix} \quad \text{on} \quad \mathbb{R}. \]

As \( M \) and \( C \) are holomorphic in \( U_c \), \(-\phi_c^{1/2}\) is conformal there, satisfies (6.19), and preserves the orientation, we see that RHP-\( P_e \)(a) is fulfilled. The above properties and (7.23) yield that RHP-\( P_e \)(b) is fulfilled as well. Finally, we get from (7.19) that

\[ \sigma_1 C(\zeta) \sigma_1 \sim \left( I + \sum_{k=0}^{\infty} \begin{pmatrix} 0 & b_k \\
0 & 0 \end{pmatrix} \right) e^{-\zeta^2} \quad \text{as} \quad \zeta \to \infty \]

uniformly in the lower and upper half-planes. Therefore, by (6.20) and since \( \phi_c(z) = \phi_c(z) - \phi_c(c) \), (7.22) satisfies (7.11) with the expansion in parenthesis being uniform on \( \partial U_c \) and closed subsets of \( C^a_{\text{birth}} \cup C^b_{\text{birth}} \), \( \alpha_e = 1/2 \), and

\[ P_{c,k}(z) = \frac{k+1/2 e^{N\phi_c(c)}}{(-\phi_c(z))^{k+1/2}} \begin{pmatrix} b_k & 0 \\
0 & 0 \end{pmatrix} \]

(again, notice that \(|e^{\phi_c(c)}| = 1|\)).
7.6. Riemann-Hilbert problem with small jumps. Set \( \Sigma_R := \left\{ \Gamma_i(e^{\pi i} \infty, a) \cup J_+ \cup \Gamma_i(b, e^{\pi i/3} \infty) \right\} \cap D \cup \left\{ \partial U_e \right\} \), where \( e \) runs over \( a \) and \( b \) as well as \( c \) when \( t \in \partial O_{\text{one-cut}} \) (in what follows, we shall always understand the symbol \( \partial_e \) this way), see Figure 14. Consider RHP-\( R \):

(a) \( R \) is holomorphic in \( \mathbb{C} \setminus \Sigma_R \) and \( \lim_{z \to \infty} R(z) = I \);

(b) \( R \) has continuous traces on \( \Sigma_R \) that satisfy

\[
R_+(s) = R_-(s) \begin{cases} 
P_c(s)M^{-1}(s), & s \in \partial U_e, \\
M(s) \begin{pmatrix} 1 & \frac{1}{2(N-n)}(s) \end{pmatrix} & s \in J_+ \cap D,
\end{cases}
\]

where \( \partial U_e \) is oriented clockwise, \( M \) is given by (7.7), and \( P_c \) is given by (7.10), (7.14), (7.20), or (7.22) depending on \( e \); as well as

\[
R_+(s) = R_-(s)M(s) \begin{pmatrix} 1 & \frac{1}{2(n-N)}(s) \end{pmatrix} M^{-1}(s),
\]

for \( s \in \Gamma_i(b, e^{\pi i/3} \infty) \cap D \) with \( e = b \) and for \( s \in \Gamma_i(e^{\pi i} \infty, a) \cap D \) with \( e = a \) (observe that \( M^{-1} \) is well defined since \( \det(M) \equiv 1 \).

\[\Gamma_i(b, e^{\pi i/3} \infty)\]
\[\Gamma_i(e^{\pi i} \infty, a)\]
\[\partial U_c\]
\[\partial U_b\]
\[J_+\]
\[J_-\]

Figure 14. The contour \( \Sigma_R \) (continuous lines). The dashed lines represent the part of \( \Gamma_i \) that does not belong to \( \Sigma_R \).

Let us show that the jump matrices in RHP-\( R \) are uniformly close to \( I \). To this end, set

\[
(7.25) \quad \Delta := R_-^{-1}R_+ - I
\]

to be the deviation of the jumps of \( R \) from the identity matrix.

Firstly, it follows from RHP-\( R \) and (7.11) with \( P_{e,k} \) given by (7.12), (7.15), (7.21), or (7.24) that

\[
(7.26) \quad \Delta \sim N^{-\alpha_e} \sum_{k=0}^{\infty} \left( MF^{(n-N)\sigma_3} P_{e,k} F^{(N-n)\sigma_3} M^{-1} \right) \text{ on } \partial U_e.
\]

The above expansions of \( \Delta(s) \) are uniform in \( s \) on each \( \partial U_e \). Moreover, the expansions on \( \partial U_a \) and \( \partial U_b \) are also locally uniform in \( \mathcal{O}_{\text{one-cut}} \) by (6.25) and (6.27). Furthermore, the expansion on \( \partial U_e \) is uniform on compact subsets of \( C_{\text{split}}, C_{\text{birth}}^0 \), and \( C_{\text{birth}}^0 \) by (6.25) and a compactness argument applied to \( \max_{x \in \partial U_e} |F^{\pm 1}(s)| \). In addition, the expansion on \( \partial U_e \) is uniform on closed subsets of \( C_{\text{birth}}^0 \) when \( n = N \) because the term \( F^{(n-N)\sigma_3} \) is no longer present. Altogether, we get by looking at the first term in expansion (7.26) that

\[
(7.27) \quad \|\Delta\|_{L^\infty(\omega_0, \partial U_e)} \leq C_0(t, \delta) N^{-\alpha_e}, \quad \alpha_e = \min \alpha_e, \quad \delta := \min \delta_e,
\]

where the constants \( \delta_e \) were introduced in (6.6) and (6.18), \( C_0(t, \delta) \) can be chosen to depend continuously on \( t \) and \( \delta \) with additional property of being bounded as \( t \to \infty \) for each fixed \( \delta > 0 \) when \( n = N \).
Secondly, since $\Gamma_1 \setminus J_t$ consists of orthogonal trajectories of $-Q(z)\,dz^2$, it holds by (6.2) that $\phi_e(s) < 0$ on the corresponding part of $(\Gamma_1 \setminus J_t) \cap D$. More precisely, there exists a constant $0 < C_1(t, \delta) < 1$ such that

$$ (7.28) \quad |F^{2(n-N)}(s) e^{N\phi_e(s)}| < C_1^N(t, \delta), \quad s \in [\Gamma_1 \setminus J_t] \cap D, $$

for all $N$ large. Since the quantities on the left-hand side of (7.28) depend on $t$ continuously, one can clearly choose $C_1(t, N)$ to be a continuous function of $t$ and $\delta$. Hence, a simple compactness argument shows that the estimate (7.28) is $(s, t)$-locally uniform in addition. Notice that $\phi_e(s)$ is monotone on each connected piece of $\Gamma_1 \setminus (J_t \cup \{c\})$. Therefore, $|e^{N\phi_e(s)}|$ achieves its largest value on $(\Gamma_1 \setminus J_t) \cap D$ either at $c$ when $c$ belongs to $\Gamma_1$ or on $\partial D$. Then, assuming $n = N$, it follows from the properties of the function $\rho(t)$ in (6.20) and the way we construct the conformal maps in (6.11) and (6.19) that $C_1(t, N)$ is bounded away from 1 on closed subsets of $C^u_{\text{birth}}$ and $C^b_{\text{birth}}$, and subsets $T \subset O_{\text{one-cut}}$ satisfying (4.1). That is, (7.28) is strongly $(s, t)$-locally uniform in the notation of Definition 4.2.

Lastly, recall also that the arcs $J_{\pm}$ were chosen so that $\Re(\phi_e(s)) > 0$ on $J_{\pm} \cap D$. In fact, we can choose them to be level lines of $\Re(\phi_e)$. Clearly, the maximal value will depend on the maximal value of $\Re(\phi_e)$ on $\partial U_{\pm} = \partial U_{\epsilon}$ when $t \in C_{\text{split}}$ as well as $\Re(\phi_e(c))$. Therefore, there exists a constant $0 < C_2(t, \delta) < 1$ such that

$$ (7.29) \quad |F^{2(N-n)}(s) e^{-N\phi_e(s)}| < C_2^N(t, \delta), \quad s \in J_{\pm} \cap D. $$

Again, it holds that $C_2(t, \delta)$ depends on its parameters continuously and is bounded away from 1 when $t$ belongs to closed subsets of $O_{\text{one-cut}} \setminus \{(e^{2\pi i/3} c)^+ \}$ and $n = N$.

Summarizing, we get from (7.26), (6.25), (7.28), and (7.29) that

$$ (7.30) \quad \Delta = O(\max \{C_1^N(t, \delta), C_2^N(t, \delta)\}) \text{ on } \Sigma_R \setminus \partial U_{\epsilon}. $$

Estimates (7.27) and (7.30) show that $\Delta$ is uniformly close to zero on $\Sigma_R$. Since the entries of $\Delta$ are geometrically small as $\Gamma_1 \ni s \to \infty$, $\Delta$ is close to zero in $L^2$-norm as well. Then it follows from the same analysis as in [14, Corollary 7.108] that $R$ exists for all $N$ large and

$$ (7.31) \quad |R - I| \leq c_0(t, \delta) N^{-\alpha_1} $$

in any matrix norm, where $c_0(t, \delta)$ continuously depends on $t$ and $\delta$, blows up as $\delta \to 0$ or $t \to \infty$, but is bounded as $t \to \infty$ along either $C^u_{\text{birth}}$, $C^b_{\text{birth}}$, or subsets $T \subset O_{\text{one-cut}}$ satisfying (4.1) when $n = N$.

7.7. Solution of RHP-Y. Given $R$, the solution of RHP-$R$, it is straightforward to verify that RHP-$S$ is solved by

$$ (7.32) \quad S = \begin{cases} RM & \text{in } D \setminus [\Gamma_1 \setminus J_t] \cup J_+ \cup J_- \cup \{c\}, \\ RP_e & \text{in } U_{\epsilon}. \end{cases} $$

Let $K_t$ be a compact set in $\mathbb{C} \setminus \Gamma_1$. We can always adjust quantities $\delta_t$ in (6.6) and (6.18) as well as the arcs $J_{\pm}$ so that $K_t$ lies entirely within one of the unbounded components of the complement of $\Sigma_R$. Then it follows from (7.2), (7.6), and (7.32) that

$$ (7.33) \quad Y(z) = ((b-a)/4)^{(n-N)\alpha_0} e^{-Nt_0^0 \sigma_3^2 L} R(z)M(z) e^{N(i(z;t)+t_0^0/2)\sigma_3} F^{(n-N)\sigma_3}(z) $$

on $K_t$. Subsequently, by using (4.14), (7.7), and the definition of $F$, we see that

$$ Y_{11}(z) = ((R_{11}(z)[M]_{11}(z) + [R_{12}(z)]M_{21}(z)) D^{n-n}(z) e^{\sigma_3(z;t)} $$

$$ = ([R_{11}(z) + [R_{12}(z)]F^{-1}(z))] A(z;t) D^{n-n}(z) e^{\sigma_3(z;t)}. $$

Equation (4.17) now follows from (6.28) and (7.31). To handle compact sets $K_t$ in $\mathbb{C} \setminus (J_t \cup \{c\})$, it is enough to consider only the sets belonging to sufficiently small Hausdorff neighborhood of $\Gamma_1$. In this case the curve $\Gamma_1$ can be deformed locally around $K$ in such a fashion that (7.28) still holds on a deformed curve, perhaps with a different constant. As the rest of the analysis is the same, the full claim (4.17) follows. The (strongly) $(z, t)$-locally uniform character of (4.17) follows from the continuity properties of $c_0(t, \delta)$ in (7.31).
Take now $K_t \subset \Gamma_t(a,b) \setminus \{c\}$. Then it follows from (7.2), (7.6), (7.32), and (4.14) that
\[
[Y]_{11} = |R|_{11} \left( (|M|_{11\pm} \pm |M|_{12\pm}) F^2_{\pm} e^{-N\phi z} e^{ngz} D^N_{\pm} \right) + |R|_{12} \left( (|M|_{21\pm} \pm |M|_{22\pm}) F^2_{\pm} e^{-N\phi z} e^{ngz} D^N_{\pm} \right).
\]
Hence, we get from (7.7), (6.23), (6.4), (4.14), and some algebra that
\[
[Y]_{11} = |R|_{11} (A_+ D_{+}^{N-n} e^{ngz} + A_- D_{-}^{N-n} e^{ng-}) +
+ |R|_{12} (B_+ D_{+}^{N-n} e^{ng+} + B_- D_{-}^{N-n} e^{ng-}).\]
Therefore, we deduce from the definition of $F$ that
\[
[Y]_{11} = \left( |R|_{11} + |R|_{12} F_1^{-1} \right) A_+ D_{+}^{N-n} e^{ngz} + \left( |R|_{11} + |R|_{12} F_2^{-1} \right) A_- D_{-}^{N-n} e^{ng-}.
\]
Formula (4.18) now follows from (6.28) and (7.31).

8. Asymptotic Expansions

In this section, we first improve (7.31) to a full asymptotic expansion following the technique of [16, Theorem 7.8 and Theorem 7.10]. Then we show how recurrence coefficients appear within the matrix $Y$ and use (7.33) and the expansion of $R$ to prove Theorem 4.5. Next, we discuss the so-called string equations and prove Theorem 4.8 using them. Finally, we employ Theorem 4.5 and Toda equation (1.29) to prove Theorem 4.3.

8.1. Error matrix $R$. Let us show that
\[
R(z) \sim I + \sum_{i=1}^{\infty} r_i(z; n-N) N^{-\alpha i},
\]
(strongly when $n = N$) $(z,t)$-locally uniformly in $\mathbb{C}$, see Definitions 4.1 and 4.2. Indeed, as shown in [16, Theorem 7.8], it holds that
\[
R = I + \sum_{k=0}^{\infty} C(\Delta_k(I) \Delta),
\]
where, as before, $C$ is the Cauchy transform, $\Delta$ was defined in (7.25), and
\[
C_{\Delta}(F) := C_{-}(\Delta F), \quad F \in L^2(\Sigma_R).
\]
It follows from (7.27) and (7.30) that
\[
\|C_{\Delta}\| = O(N^{-\alpha t})
\]
(strongly when $n = N$) $t$-locally uniformly. Define
\[
\Delta_i(s) := N^{-\alpha} \sum_{\kappa=0}^{l-1} \left( \frac{\partial F_{\kappa}}{\partial F_{\kappa}} (n-N)^{\sigma_1} P_{\kappa} F(n-N)^{\sigma_2} M^{-1} \right)(s) N^{-k}, \quad s \in \partial U_e,
\]
and set $\Delta_i \equiv 0$ on $\Sigma_R \setminus \partial U_e$. Observe that the coefficient next to $N^{-k}$ depends neither on $n$ nor $N$ individually, but does depend on the difference $n-N$. Clearly, it follows from (7.26) and (7.30) that $\Delta_i$ approximate $\Delta$, that is,
\[
\|\Delta - \Delta_i\|_{L^2(\Sigma_R)} + \|\Delta - \Delta_i\|_{L^2(\Sigma_R)} + \|\Delta - \Delta_i\|_{L^\infty(\Sigma_R)} = O(N^{-(\alpha t + l)})
\]
(strongly when $n = N$) $t$-locally uniformly. Define $C_{\Delta_i}$ as in (8.3) with $\Delta$ replaced by $\Delta_i$. Clearly, $C_{\Delta_i}$ satisfies (8.4). Moreover, it holds that
\[
R - I - \sum_{k=0}^{l-1} C(\Delta_k(I) \Delta_i) = O\left(N^{-\alpha_i(l+1)}\right)
\]
(strongly when $n = N$) $(z,t)$-locally uniformly in $\mathbb{C}$. Indeed, similarly to (7.31), equations (7.27), (8.4), and deformation of $\Sigma_R$ technique yield that
\[
\sum_{k=0}^{\infty} C(\Delta_k(I) \Delta) = O\left(N^{-\alpha_i(l+1)}\right)
\]
(strongly when \( n = N \)) \( t \)-locally uniformly. Furthermore, it holds by (8.6) and an analogous argument that
\[
(8.9) \quad \sum_{k=0}^{l-1} c_k^N(I) \left( \Delta - \Delta_i \right) = \mathcal{O} \left( N^{-(\alpha+1)} \right)
\]

(\( n \)) \( t \)-locally uniformly. Finally, we deduce from (8.6) and deformation of \( \Sigma_R \) technique that
\[
(8.10) \quad \sum_{k=0}^{l-1} c_k^N(I) = \mathcal{O} \left( N^{-(2\alpha+1)} \right)
\]

(\( n \)) \( t \)-locally uniformly. Estimates (8.8)–(8.10) imply (8.7). Now, to derive (8.1), it only remains to notice that \( c_k^N(I) \) has an asymptotic expansion in powers of \( N^{-\alpha} \), whose coefficients up to the order \( l \) do not depend on \( l \) or \( n, N \) individually.

8.2. Recurrence Coefficients. It follows from (1.27) and (1.28) that
\[
\begin{aligned}
\gamma_n^2(t, N) &= h_n(t, N)/h_{n-1}(t, N), \\
\beta_n(t, N) &= (P_n)_{n-1} - (P_{n+1})_{n},
\end{aligned}
\]

where we write \( P_n(z; t, N) = z^n + \sum_{k=0}^{n-1} (P_k)_{k} z^k \). Hence, we get from (7.1) that
\[
Y(z)z^{-n_{\sigma_3}} = I + \frac{1}{z} \left( (P_n)_{n-1} - \frac{h_n}{h_{n-1}} \right) + \mathcal{O} \left( \frac{1}{z^2} \right) = I + \frac{Y_1(n; t, N)}{z} + \mathcal{O} \left( \frac{1}{z^2} \right).
\]

Therefore,
\[
(8.11) \quad \begin{aligned}
\gamma_n^2(t, N) &= \left[ Y_1(n; t, N) \right]_{12} \left[ Y_1(1; t, N) \right]_{21}, \\
\beta_n(t, N) &= \left[ Y_1(n; t, N) \right]_{11} - \left[ Y_1(1; t, N) \right]_{11}.
\end{aligned}
\]

We deduce from (7.33), (4.14), (3.7), and the definition of \( F \) that
\[
Y(z)z^{-n_{\sigma_3}} = \left( \frac{b-a}{4} \right)^{(n-N)_{\sigma_3}} e^{-N\ell_{\sigma_3}/2} \left( I + \frac{R_1(n; t, N) + M_1(t)}{z} + \mathcal{O} \left( \frac{1}{z^2} \right) \right) e^{-N\ell_{\sigma_3}/2} \left( \frac{b-a}{4} \right)^{(N-n)_{\sigma_3}},
\]

where we write
\[
\begin{aligned}
e^{g(t, z)} &= z + G_1(t) + \mathcal{O}(z^{-1}), \\
D(z; t) &= 1 + z^{-1} D_1(t) + \mathcal{O}(z^{-2}), \\
K(z) &= I + z^{-1} K_1(n; t, N) + \mathcal{O}(z^{-2}), \quad K \in \{ M, R \}.
\end{aligned}
\]

In fact, it follows from (4.12) and (6.22) that \( D_1(t) = 1/4x^2(t) \), and analogously we deduce from (4.14) and (4.16) that \( G_1(t) = -x(t) + 1/4x^2(t) \). Further, using (7.7), (4.15), and (3.7) we see that
\[
M_1(t) = \begin{pmatrix}
0 & -1/\sqrt{2x(t)} \\
1/\sqrt{2x(t)} & 0
\end{pmatrix},
\]

Therefore (8.11) can be rewritten as
\[
(8.12) \quad \begin{aligned}
\gamma_n^2(t, N) &= -1/(2x(t)) + (\left[ R_1 \right]_{12} - \left[ R_1 \right]_{21})/\sqrt{2x(t)} + \left[ R_1 \right]_{12} \left[ R_1 \right]_{21}, \\
\beta_n(t, N) &= x(t) + \left[ R_1(n; t, N) - R_1(n+1; t, N) \right]_{11}.
\end{aligned}
\]

Hence, (4.4) follows from (8.1) and (8.12). Moreover, as \( \gamma_n^2(t, N) \) is expressed only through \( R_1(N; t, N) \), its expansion is strongly \( t \)-locally uniform.

To see the analyticity of \( G_k(t; n-N) \) and \( B_k(t; n-N) \) in \( O_{\text{one-cut}} \), we need to examine the dependence of \( R_1 \) on \( t \). To this end, write
\[
(8.13) \quad R_1 = -\frac{1}{2\pi i} \oint_{\partial U_n} \left( \sum_{k=0}^{l-1} c_k^N(I) \Delta_i \right) (s) ds + \mathcal{O} \left( N^{-(l+1)} \right),
\]
which we can do according to (8.7), where $\Delta_1$ is given by (8.5). Notice that on each $\partial U_c$ the function $\Delta_1$ is a trace on $\partial U_c$ of a meromorphic matrix-valued function in $U_c$ with a single pole at $e$. Indeed, it is clear that $\Delta_1$ is holomorphic in $U_c \setminus J_1$ and on $J_1$ it holds that

$$\Delta_{I_+} = N^{-\alpha_4} M \cdot F_{-}^{(n-N)\sigma_4} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \sum_{k=0}^{l-1} P_{e,k} N^{-k} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} F_{+}^{(N-n)\sigma_4} M_{-+}^{-1}$$

$$= N^{-\alpha_4} M \cdot F_{-}^{(n-N)\sigma_4} \left( \sum_{k=0}^{l-1} P_{e,k} N^{-k} \right) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} F_{+}^{(N-n)\sigma_4} M_{-+}^{-1} = \Delta_{I_-},$$

where the first and the last equalities follow from RHP-$M$ (b) and (6.23) while the second can be verified by using the explicit expressions (7.12) and (6.9), (7.15) and (6.14), (7.21) and (6.17). Hence, $\Delta_1$ is indeed meromorphic in each $U_c$ with a pole at $e$. From this, it is easy to see that $C_{\Delta_1, (I)}^{\Delta_1}$ is a trace on $\partial U_c$ of a meromorphic matrix-valued function in $U_c$ with a single pole at $e$. In particular, the integral in (8.13) does not depend on the radii of the disks $U_c$. Thus, its $t$-dependence comes only from the points $a, b, c$ and the conformal maps constructed in (6.11), (6.14), (6.17), and (6.19). It follows from Proposition 3.1 that $a(t), b(t), c(t)$ are holomorphic functions of $t \in \partial U_{\text{one-cut}}$ with holomorphic continuations across each of the arcs $C_{\text{split}}, C_{\text{birth}}^a$, and $C_{\text{birth}}^b$. The conformal maps $(-\phi_c)^{2/3}$ and $(-\phi_b)^{2/3}$, see (6.11) and (6.2), have the same type of dependence on $t$. Thus, we indeed see that the functions $R_t$ are analytic functions of $t \in \partial U_{\text{one-cut}}$.

Let now $n = N$. The first claim of (4.6) was derived in [7, Corollary 4.2], Observe that to show the second claim, it is enough to prove that

$$R_1 = \sum_{1 \leq j \leq l \leq l-1} \left( \begin{array}{c} p_{2j+1} \\ q_{2j+1} \\ p_{2j+1} \end{array} \right) N^{-2j-1} + \sum_{2 \leq j \leq l \leq 1} \left( \begin{array}{c} p_{2j} \\ q_{2j} \\ p_{2j} \end{array} \right) N^{-2j+1} + \mathcal{O}(N^{-(l+1)})$$

for some constants $p_k, q_k$, as then it obviously holds that $[R_1]_{12} = [R_1]_{21}$ and $[R_1]_{12}[R_1]_{21}$ have asymptotic expansions only in even powers of $N^{-1}$. Using (7.12) and (7.7), it is tedious but straightforward to verify that the expansion for $\Delta_1$ has exactly the same form as the right-hand side of (8.14) (without $\mathcal{O}$-term), where

$$\begin{align*}
p_{2j} &\mapsto (s_{2j} + t_{2j})(-\phi_c/2)^{-2j}, \\
q_{2j} &\mapsto e_e(s_{2j} - t_{2j})(-\phi_c/2)^{-2j}, \\
p_{2j+1} &\mapsto 2iAB(s_{2j+1} + t_{2j+1} + e_e(s_{2j+1} - t_{2j+1}))(-\phi_c/2)^{-2j-1}, \\
q_{2j+1} &\mapsto -2AB(e_e(s_{2j+1} - t_{2j+1}) + s_{2j+1} + t_{2j+1})(-\phi_c/2)^{-2j-1},
\end{align*}$$

on $\partial U_c$. Clearly, $C_{\Delta_1, (I)} = C_{-\Delta_1}$ also has the same form as the right-hand side of (8.14). Another boring computation shows that the product $C_{\Delta_1, (I)}^{\Delta_1}$ has the same form as well. By induction, we get that all the summands under the integral sign in (8.13) have this form, from which (8.14) clearly follows.

8.3. String Equations. To prove Theorem 4.8, we need to introduce discrete string equations (see, e.g., [9]):

$$\left\{ \begin{array}{l}
\gamma_n [V''(Q)]_{n, n-1} = \frac{n}{N}, \\
[V'(Q)]_{nn} = 0,
\end{array} \right.$$
the second variable. Assuming that \( \sim \) expansion of \( \gamma \) with the expansion valid locally uniformly in both variables. Then the constant term in the last equality holds on a set with a limit point in \( N \).

\[
\begin{align*}
\gamma_n [-Q^2 + t I]_{nn-1} &= \frac{n}{N}, \\
[-Q^2 + t I]_{nn} &= 0.
\end{align*}
\]

(8.15)

To prove (4.9) using (8.15), let us set

\[
v := \left( \frac{n + 1/2}{N} \right)^{-2/3} \quad \text{and} \quad u_* := \left( \frac{n}{N} \right)^{-2/3} = v \left( 1 - \frac{v^{3/2}}{2N} \right)^{-2/3}.
\]

Then for all \( N \) large, the value \( \hat{B}_k(t, u_*) \) can be computed as a series

\[
\hat{B}_k(t, u_*) = \sum_{i=0}^{\infty} \frac{\partial^i B_k}{\partial t^i} (t, v) v^i \left( 1 - \frac{v^{3/2}}{2N} \right)^{-2/3}.
\]

Using the Taylor expansion of \((1 - x)^{-2/3}\) at the origin, we can rewrite the above expression as a series in powers of \( N \) with coefficients that are holomorphic in \( N \) functions. Thus, (4.8) can be equivalently written as

\[
\beta_n(t, N) \sim \sum_{k=0}^{\infty} \hat{B}_k(t, v) N^{-k},
\]

where the functions \( \hat{B}_k(t, v) \) are holomorphic in \( N \). Hence, to prove (4.9) we need to show that \( \hat{B}_{2j-1}(t, v) \equiv 0 \) in \( N \). To this end, let us represent each \( \hat{B}_k(t, v) \) as a series in powers of \( N^{-1} \):

\[
\hat{B}_k(t, v) = \sum_{j=0}^{\infty} \hat{B}_{k,j}(t, u_*) N^{-j}, \quad \hat{v} = \left( \frac{n + 1/2}{N} \right)^{-2/3} = u_* \left( 1 + \frac{u_*^{3/2}}{2N} \right)^{-2/3}.
\]

Notice also that

\[
\hat{B}_{k,0}(t, u) = \hat{B}_k(t, u) \quad \text{and} \quad \hat{B}_{0,0}(t, u) = x(tu) / \sqrt{u}.
\]

Then it also holds that

\[
\hat{B}_k(t, w) = \sum_{j=0}^{\infty} \hat{B}_{k,j}(t, u_*) (-N)^{-j}, \quad \hat{w} = \left( \frac{n - 1/2}{N} \right)^{-2/3} = u_* \left( 1 - \frac{u_*^{3/2}}{2N} \right)^{-2/3}.
\]

Hence, we get that

\[
\beta_n(t, N) + \beta_{n-1}(t, N) \sim 2 \sum_{k=0}^{\infty} \left( \sum_{j=0}^{\infty} \hat{B}_{k,2j}(t, u_*) N^{-2j} \right) N^{-k},
\]

with the expansion valid locally uniformly in both variables. Then the constant term in the expansion of \( \gamma_n^2(\beta_n-1 + \beta_n) \) is equal to

\[
-\frac{2\hat{B}_{0,0}(t, u_*)}{u_* x(u_*)} = -\frac{u_*^{-3/2}}{2} = -\frac{n}{N}
\]

by (4.8) and (8.16). Thus, it follows from the first relation in (8.15) that the rest of the terms in the expansion of \( \gamma_n^2(\beta_n-1 + \beta_n) \) must be equal to zero. The \( N^{-1} \)-term is given by

\[
-\frac{\hat{B}_{2l+1,0}(t, u_*)}{u_* x(u_*)} = -\frac{\hat{B}_{2l+1}(t, u_*)}{u_* x(u_*)}, \quad l = 0,
\]

by (4.8), (8.17), and (8.16). This implies that \( \hat{B}_1(t, u_*) = 0 \). As we can vary \( n \) and \( N \), the last equality holds on a set with a limit point in \( N \). Hence, \( \hat{B}_1(t, \cdot) \equiv 0 \) by holomorphy in the second variable. Assuming that \( \hat{B}_{2l-1}(t, \cdot) \equiv 0 \) for all \( l \leq L \), we get from (4.8), (8.17), and (8.16) that the \( N^{-(2L+1)} \)-term in the expansion of \( \gamma_n^2(\beta_n-1 + \beta_n) \) is given by (8.18) with
$l = L$. Previous argument yields that $\tilde{B}_{2L+1}(t, \cdot) \equiv 0$ and the desired claim now follows from the principle of mathematical induction.

8.4. Free energy. In [6, Proposition 5.1], it was shown that the free energy $F_N(t)$ and the recurrence coefficient $\gamma_N(t, N)$ satisfy Toda equation (1.29) for all $t > t_{cr}$. It was further shown in [6] that

$$F_N(t) = \frac{2}{3} t^{3/2} - \frac{1}{4} \log(4t) + \int_t^\infty \int_\infty^\tau \left( \gamma_N^2(\sigma, N) - \frac{1}{2\sqrt{\sigma}} - \frac{1}{4\sigma^2} \right) d\sigma d\tau,$$

where the integrals are taken along positive reals. It was also proved in [6] that an asymptotic expansion for $F_N(t)$ can be obtained by simply plugging the asymptotic expansion for $\gamma_N^2(t, N)$ into (8.19) and integrating term by term; that is, (4.2) is valid uniformly on closed subsets of $(t_{cr}, \infty)$, where the functions $F^{(2k)}(t)$ can be computed via the following equations:

$$F^{(0)}(t) = \frac{2}{3} t^{3/2} - \frac{1}{4} \log(4t) + \int_t^\infty \int_\infty^\tau \left( -\frac{1}{2x(\sigma)} - \frac{1}{2\sqrt{\sigma}} - \frac{1}{4\sigma^2} \right) d\sigma d\tau,$$

(8.20)

$$F^{(2k)}(t) = \int_\infty^t \int_\infty^\tau G_{2k}(\sigma; 0) d\sigma d\tau, \quad k \geq 1,$$

(the integrals in (8.20) are well defined as it was shown that $G_{2k}(t; 0) = \mathcal{O}(t^{-7/2})$ and $x(t) = -\sqrt{t} + \frac{1}{2\sqrt{t}} + \mathcal{O}(t^{-5/2})$ uniformly as $t \to \infty$).

Since $Z_N(t)$ is an entire function of $t$, the free energy $F_N(t)$ is a meromorphic function of the parameter $t$. Hence, Toda equation (1.29) extends to the entire parameter plane. Recall that $\gamma_N^2(t, N)$ are holomorphic functions of the parameter $t$ on each closed subsets of $\mathcal{O}_{\text{one-cut}}$ satisfying (4.1) for all $N$ large enough (depending on the subset). Hence, using (3.4) and some algebra, we can rewrite (8.19) as

$$F_N(t) = 1 - \frac{2}{3} x^3(t) - \frac{1}{2} \log \left( -2x(t) \right) + \int_t^\infty \int_\infty^\tau \left( \gamma_N^2(\sigma, N) + \frac{7x'(\sigma)}{6} + \frac{2x''(\sigma)}{6} \right) d\sigma d\tau,$$

where $x'(t)$ is the derivative of $x(t)$ with respect to $t$. Hence, for any closed subset $T \subset \mathcal{O}_{\text{one-cut}}$ satisfying (4.1) there exists a constant $N(T)$ such that the functions $F_N(t)$ are holomorphic on $T$. Similarly, we see that the functions $F^{(2k)}(t)$ are in fact holomorphic in $\mathcal{O}_{\text{one-cut}}$ and can be holomorphically extended across $C^a_{\text{split}}, C^b_{\text{birth}},$ and $C^b_{\text{birth}}$. This, in particular, gives formula (4.3). Thus,

$$F_N(t) - \sum_{k=0}^{K-1} F^{(2k)}(t) N^{-2k} = \int_\infty^t \int_\infty^\tau \left( \gamma_N^2(\sigma, N) - \sum_{k=0}^{K-1} G_{2k}(t; 0) N^{-2k} \right) d\sigma d\tau = \mathcal{O}(N^{-2K})$$

uniformly on closed subsets of $\mathcal{O}_{\text{one-cut}}$ satisfying (4.1), which implies that asymptotic expansion (4.2) does indeed hold in $\mathcal{O}_{\text{one-cut}}$ as claimed.
